# CARTOGRAPHY AND THE UNIVERSITIES

THE primary concern of geography is to take accurate note of the spatial relationship existing between environmental phenomena which are significant in the organized life of mankind, and its philosophy is devoted to interpreting the interaction of man and his habitat. Cartography has a special and close relationship with geography.

Modern geography is becoming more and more an exact science using quantitative methods in regional analysis. To studies of this kind the map, chart and diagram are fundamental and, because of this, cartographical studies rightly occupy an important place in the geographer's training. The map is the geographer's chief tool. In its simplest conception it is a conventionalized representation of some aspect of the earth's pattern so that the larger patterns are reduced in such manner that they can be comprehended in one person's view. The geographer seeks to interpret, understand and account for the facts displayed. To bring these fundamental materials for study into existence, two phases are involved. First there must be measurement by the *surveyor* of the elements of the total environment that are to be portrayed : the configuration of the land or of the sea bottom, the weather, climate, geology, social, cultural and demographic features, etc. The organized measurement of the elements of environment is properly the work of specialists such as the topographical and hydrographic surveyor, the meteorologist, geologist, economist, anthropologist and so on, each developing a high degree of specialist skill in technique and refinement of equipment, and also often finding government authority and support necessary for the adequate performance of their duties. This being done, it is the *cartographer's* business proper to collect and use these measurements, and render the data in such a way that they may be accurately and fully but clearly depicted. Many sciences provide the cartographer with his material, and although he is not primarily concerned with observational practice, yet he must possess a knowledge of the methods of the sciences sufficient to enable him to check or appraise the value of the data supplied.

A geographer intending to carry out his own investigations into man's physical environment and his relationship with it will often need to make his own measurements, and though he may not do so with the refinement and equipment of the professional specialist surveyor or investigator, he will none the less be using exactly the same methods and principles. The geographer, too, needs to be able to give clear and correct graphic expression to his ideas. Hence a knowledge of, and some working practice in, the methods, technique and limitations of both the survey and cartographic aspect become essential if the geographer is to obtain and give a true interpretation of the information he is handling.

In order to ascertain if adequate training were being given in these aspects, it was decided after a discussion during the Cambridge meeting in 1938 of the

British Association for the Advancement of Science, that the Conference of Heads of University Departments of Geography should endeavour to obtain information about cartographical work conducted in British universities and the universities of the Empire. A *questionnaire* on 'laboratory work' was accordingly drawn up and sent out to departments of geography in the various universities.

So far as the universities of Great Britain are concerned, it is probably true that most departments devote an adequate amount of time to cartographical studies, such work representing 30–40 per cent of the geography time-table in each of the three years of an honours degree course. But generally speaking, the topics treated are very similar, resulting in a surprising lack of differentiation among departments which in other ways work on distinctive lines. The general scheme is practical map work, map reading and the interpretation of topographical sheets; the cartographic analysis of maps (British and foreign) on different scales; the cartographic representation of economic and other statistical data; geological, meteorological and climatological maps, and exercises based on them, and varying amounts of surveying. No doubt the quality of the cartographic work could be improved, but this would be conditional on equipment and properly qualified staff being available.

That cartography in university departments of geography in Great Britain has been thought mainly to consist of map reading and interpretation, an understanding of the properties of different projections, the elementary methods of survey and the construction of statistical maps and diagrams is understandable, in that these ought, if properly taught, to provide the geographer with a training sufficient to enable him to carry out simple surveys and to use and appreciate maps scientifically. The major deficiency in the courses offered lies in the paucity or absence of training in those special techniques, judgment, style, etc., that characterize the range of operations that must take place between the completion of the survey and the placing of the published map or chart in the hands of the geographer.

An improvement in the quality of cartographic instruction could be secured without an extension of time already devoted to this side of the geography course by the adoption of a carefully thought out syllabus which would ensure that all aspects of cartographic studies receive adequate treatment—all important branches of surveying, office compilation and drawing and map production as well as map use and interpretation. In suggesting improvements for the geographer, the possibility of building up, on this foundation, courses which will cater for the needs of the specialist cartographer should not be overlooked. Before the War no advanced course of cartographical studies could be taken in any British university. At Cambridge, instruction in advanced topographic and geodetic surveying was available in Part II of the Geographical Tripos; but this course was largely designed for intending entrants into the Colonial Survey Service, and as such was not concerned with the preparation and production of maps and diagrams recording all the elements in man's environment and his activities in economic, social and political affairs.

The incidence of war has created an increased demand for the specialist cartographer. Government departments have had serious difficulties in satisfying their requirements, and on occasions it has proved impossible to find people adequately trained for cartographic posts. A demand for the services of trained cartographers exists not only in the older Government departments producing maps and charts from fundamental surveys, but also in the newer ministries now largely concerned with the work of planning and reconstruction. The oldest department is the Ordnance Survey (dating back to 1791), and this is charged with the responsibility of the national survey, from cadastral maps to general-purpose sheets on smaller scales. The staff is partly civil and partly military, the latter filling the higher posts and being trained at Royal Engineers schools such as Woolwich and Chatham.

Of a somewhat similar vintage is the Hydrographic Department, founded in 1795, which is responsible for the preparation of charts for the Royal Navy and merchant fleet. Here again service and civilian personnel are to be found, but there is a more rigid demarcation of duties: office and production work is largely a civil matter, the hydrographic survey being undertaken by naval personnel of the surveying service.

The comparable unit in the War Office is the Directorate of Military Survey and Geographical Section General Staff, which dates from 1855. Originally the section had an imperial function, as it was largely responsible for the preparation and production of maps of the Colonies and other poorly surveyed parts of the world in which Great Britain had a special interest. This work has diminished, however, as each Colony and Dominion has taken over its own survey, and now the organization is chiefly concerned with the compilation and supply of maps to the Army; it has recently acquired the responsibility for the preparation and supply of aeronautical maps to the Royal Air Force. Like the Ordnance Survey, its staff is partly civil and partly military, the latter being drawn from the Royal Engineers.

The newer departments, the development of which has demanded, or might demand, cartographic staff, include the Ministries of Home Affairs and Home Security, Information, Town and Country Planning, Transport, Health, and Agriculture and Fisheries, and the Board of Trade.

In the war-time expansion of activity, the Service departments have looked to the universities for suitably trained 'specialists'; but not having recruited personnel from them hitherto, there were no specialist courses, and apart from those teaching cartography in the schools of geography few were found. The situation in the universities of Great Britain is now generally worse than before the War; but one advantage at least has accrued, in that a close knowledge of the needs of these departments has been gained by the university teachers absorbed into them.

Two broad conclusions emerge. In the first place, there are undoubted grounds for an improvement in quality of the cartographical training made available for geographers. Secondly, in view of the probable continued post-war need for specialist cartographers —personnel best recruited from geographers with a good mathematical training—it seems likely that the Government departments will look to the universities of Great Britain when making such professional appointments. It is therefore not too early to consider an investigation into the probable needs of these departments and the possibility of meeting such needs, not only by the desirable general raising of the standard of cartographical teaching, but also by the creation of advanced courses at selected universities.

## A SHORTER HISTORY OF SCIENCE

A Shorter History of Science
By Sir William Cecil Dampier. Pp. x+190+9 plates. (Cambridge: At the University Press, 1944.) 7*s*. 6*d*. net.

SIR WILLIAM DAMPIER has now published a shorter and easier version of his very successful "History of Science". In the preface he says that the readers he has in mind are, first, that rather elusive creature the 'general reader', and second, those more definable readers who occupy the higher forms of schools. They will either be science students whose science can be broadened, or students of the humanities who need an idea of the place of science in human life. The book should fulfil these requirements very well indeed.

The new volume is less than a third of the length of the earlier one. Thanks to narrow margins, no references in footnotes and thin paper, it can be put into one's pocket. In spite of this, the print is clear and not crowded, and room has been found for nine plates. Six of these are portraits of men of science —Archimedes, Leonardo da Vinci, Galileo, Newton, Darwin and Rutherford. The first portrait is perhaps not very authentic. The last is authentic enough, but is a photograph with that strained expression often seen on passports and not at all characteristic of Rutherford.

The process of compression has been carefully done. By omitting minor lines of investigation and the work of minor contributors, the account has on the whole been made more readable, without any great loss for a book that is not meant to be a work of reference and that supplies a good select bibliography. There is less philosophical discussion but enough to give an outline of that aspect of scientific thought. Parts have been rewritten and some definitely improved, but of course a good deal of the compression has been a matter of scissors and paste. The earlier chapters up to the end of the eighteenth century are highly successful. If the later ones are not quite so good, that is because the immense mass of detail to be considered raises much harder problems. In a few cases compression has gone to the length of obscurity, as in the solitary mention of the work of Langmuir and Adam on surface films (p. 135). The statement about von Baer, the embryologist, at the end of p. 114, has become misleading by the omission of statements that explain and qualify it in the larger book. The probability curves shown on pp. 96 and 124 without adequate explanation in the text or under the figure are likely to mystify the innocent reader. This is specially to be regretted, as these curves come into a host of modern problems. Still, these are minor blemishes and there do not seem to be many of them.

For the majority of readers, who are not going to be scientific specialists, but who want a conspectus of the development of scientific thought and practice, the book seems admirably fitted. For those young people who are going to devote themselves to scientific investigation it has one defect, though one it shares with almost anything they are likely to read about the progress of science. That is, that this progress is made to look like an unbroken series of triumphs. Before long these people will discover that the experimental method consists in doing fifty things wrong before doing one right. It might be a help to them (to mention one case only) to hear how it happened that "the incomparable Mr. Newton" himself made one serious mistake and devoted years to chemical experiments which yielded no results. There is no need to go to the other extreme of the cynic who said that "science consists of theories, which nobody believes except the man who first thought of them, and facts, which everybody believes except the man who has last investigated them". Nevertheless, the young do tend to take a rose-coloured view of things, and it is part of the duty of their elders to disabuse them. A. D. RITCHIE.

## BIBLIOTHECA CUSHINGIANA

The Harvey Cushing Collection of Books and Manuscripts
(Publication No. 1. Historical Library, Yale Medical Library.) Pp. xvi+207. (New York: Schuman's, 1943.) 8.50 dollars.

WHEN Prof. Cushing bequeathed his remarkable library to his old University of Yale, he set aside a fund to be used in cataloguing portions of the collection. The advisory board of the historical library, however, decided to employ this fund in preparing a short-title list of the *entire* collection. Whether it was advisable to do this, instead of concentrating on a list of only the rarer and more important items, *with full collations*, was doubtless considered. Cushing's bio-bibliography of Andreas Vesalius, published posthumously, does indeed include such collations of the relevant Vesaliana, and this to some extent favours the decision of the members of the advisory board, who were not in a position to ignore considerations of expense, or to indulge in duplication. Prof. J. F. Fulton, who is devoted to the memory of Cushing, and is himself a learned and experienced bibliographer, favoured the solution adopted, and it will be wise to respect his judgment, although a volume comparable in plan with the Bibliotheca Osleriana would have been most welcome.

The library includes 77 early manuscripts, 168 *incunabula*, and some 7,500 books, pamphlets and separates. It is therefore not a large collection, but on the other hand it is relatively very rich in the rarest and most desirable works. To assemble such a library, in times when it was possible, postulated the possession of ample means, of knowing what to

buy and how to find it, and above all of a dogged pertinacity almost superhuman. All three conditions were abundantly exemplified in Cushing and his friend Osler, and the result was the formation of two of the most notable private scientific libraries of modern times. A few of Cushing's rarities, apart from his unique collection of Vesaliana, are: Aselli on the lacteals, 1627; Berengarius' Isagoge, 1522; Caius on dogs, 1570; Canano on the muscles, 1541; Coiter's comparative anatomy, 1573–75; Dryander's anatomy, 1536–37; Estienne's anatomy, 1545; Harvey on the circulation, 1628; Mondinus' anatomy, 1538; Rabelais' Pantagruel, 1546; Redi on insects, 1668; Vicary's anatomy, 1587; and Wolff's Inaugural Dissertation, 1759. There are, of course, notable gaps, some of which are surprising, since they could have been readily filled. Such are Haller's "Bibliotheca Anatomica" and "Elementa Physiologiae", both of which Cushing must have frequently consulted. Havers on the bones, Tyson's chimpanzee, Willis on the soul of brutes and the "Acta Medica Hafniensia" are also wanting.

The volume has been very well printed on good paper and is suitably bound. F. J. COLE.

## WEST INDIAN ARCHÆOLOGY

### Yale University Publications in Anthropology, Nos. 25 and 26

The Ciboney Culture of Cayo Redondo, Cuba, by Cornelius Osgood; Archeology of the Maniabon Hills, Cuba, by Irving Rouse. Pp. 252+14 plates. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1942.) 23*s*. 6*d*. net.

THE two areas of excavation under review lie to the west and east of Cuba respectively. Cayo Redondo is a swamp island close to the sea at the head of Guadiana Bay; the Maniabon hills have yielded a number of kitchin midden sites and a cave habitation. Everything earlier than the coming of the Spaniards is, of course, prehistoric, and the early story of Cuba has still to be written in detail. But the generalized outline is known and much suggestive information can be obtained from the volume under review.

It would seem that at some unknown date—perhaps during the first millennium of our era—a people from North America filtered into the "islands" and occupied Cuba. They have been called the Ciboney. Very similar to them in all main characteristics were the so-called Guayabo Blanco folk. The Ciboney introduced a very primitive culture and practised neither agriculture nor manufactured pottery. Any manifestation of art, too, is absent. Their material culture seems to have consisted mainly of objects made from shell and rough stones. Ochre, however, has been discovered, so they may have painted themselves. Their burial ceremonies are unknown though they may have deposited their dead in caves.

At a somewhat later date tribes of the Arawak group, perhaps impelled by the Caribs, penetrated up from South America and occupied most of Cuba, leaving little but small, unhealthy areas on the western coast to the earlier Ciboney. The Maniabon Hills' sites, while yielding a little Ciboney material, have mostly yielded objects left by the newcomers, and the Ciboney probably had to quit. The invaders fall into two groups chronologically, named respectively the Sub-Taino culture and the Taino culture. They practised agriculture and made pottery. This at first was beautifully decorated, but later became poorer in quality and plain. The Caribs arrived just before the Spaniards, and would doubtless have overrun both the earlier Ciboney and the Taino groups if the Europeans had not arrived in time to mop up everything themselves. Anyone interested in the "pre-conquest" Indian cultures of the West Indies should peruse this work. It is well illustrated. M. C. BURKITT.

## A STUDY OF FREEDOM

### The Machiavellians

Defenders of Freedom. By James Burnham. Pp. v+202. (London: Putnam & Co., Ltd., 1943.) 7*s*. 6*d*. net.

MR. BURNHAM is well known as the author of "The Managerial Revolution". He remarks, with a certain bitterness, of the present book that its circulation is not likely to be large. I am not sure whether Montaigne, who held himself detached from the civil wars of his day, may not have had a richer wisdom than Machiavelli; but Mr. Burnham feels that the Florentine, and his successors of the too little known Italian school, Pareto, Michels and Mosca, require this volume of homage. For Mr. Burnham's attempt to develop still further an authentic political science, following in the way of the Chicago school and its derivative, Bertrand Russell, too high praise can scarcely be given.

The thesis, of course, that the appetite for power rather than the economic appetite provides not only the major but also the master key to the interpretation of political action is, as this writer can testify, not new and will to-day be found even in the writings of Russian Marxists. An eminent Left Wing weekly journal recently, in reviewing Mr. Burnham's book, commented sub-acidulously that it made no contribution to scholarship. We may reasonably suspect that we have here a psychological defence reaction, for which doubtless Pareto would find a technical name. The fact is that the Marxists, under pressure of the results of recent psychological and anthropological research, are in full strategic retreat from their earlier material dogmatism, and the franker among them are prepared to admit that new light is possible since Marx. Our major risk is to be told that Marx invented Burnham's power theory as well as all the rest.

Mr. Burnham, in elaborating the predominance of the quest for power over the specific quest for control of the means of production as social determinant, supports his case by a historical survey from Machiavelli to Mosca. Recent American attention, not least under the guidance of Prof. Henderson, to the modern Italian school is noteworthy. In his "Managerial Revolution" Mr. Burnham gave reason to doubt whether the world is moving in the direction of "a free, classless, international society", and many events (not least in the U.S.S.R.) which have taken place since he wrote serve to bear him out. Like most pioneers, he perhaps overstressed his argument and minimized the difference caused not only by the rise to power of new families in that country, but also by the liquidation of old families compared with the managerial situation (at least at present) in western Europe and America. That is, the Communist

Revolution (like the French *bourgeois* Revolution) may be not only more real but also more distinctive, compared with the National Socialist, than he supposes. It does not, of course, follow that it is more equalitarian in its present structure, although even here the traditional Russian ideology is ambivalent (Leninist and Tsarist).

Similarly in his present brief and readable book Mr. Burnham (who, incidentally, is lecturer in philosophy in New York University) tends to overplay his argument. "Despotism is more nearly than freedom in accord with human nature" is but a half-truth. History, indeed, shows political individual freedom (usually destroyed, Aristotle observed, by popular movements in favour of majority will, leading towards tyranny) to be rarer than political authoritarianism of a pronounced type. But Pavlov's thesis that freedom is a conditional reflex or instinct remains undestroyed. All that happens is that, when men come to put first social security, the impulse for freedom—as distinct from the bellicose desire for tribal anarchy—takes other than civil forms, and leads men into the desert solitudes. Mr. Burnham's phrase involves a false antithesis and, taken precisely, will not stand up to criticism. When Mr. Burnham says that there is a universal "trend to Bonapartism", in part precipitated by the coming of war, nationalism and democratic economic needs, but not to be removed by the end of war, he is on safer ground and I agree with him. Certainly every sociologist and politician (including Mr. Cordell Hull) will be benefited by reading this highly stimulating and hard-hitting book, even if in conclusion he says, as did Mr. Hughes of Clemenceau's statement that Hughes was once a cannibal, "the report has been greatly exaggerated". Let us avoid cant. Certainly, if democracy is not to end in popular personal dictatorship (as it now shows signs of doing, not unexpectedly, in France) let us avoid cant, including the cant (of which Dr. Eric Fromm, in the "Fear of Freedom", warns us) which will not admit that many men dislike all liberty save their own.

GEORGE CATLIN.

## FRESHWATER FISHES OF CHINA

**The Fresh-Water Fishes of China**

By John Treadwell Nichols. (Central Asiatic Expeditions: Natural History of Central Asia, Vol. 9.) Pp. xxxvi+322+10 plates. (New York: American Museum of Natural History, 1943.) 9 dollars.

THE Asiatic Expeditions of the American Museum of Natural History have brought together general collections of freshwater fishes from representative localities in China, and this monograph by Dr. Treadwell Nichols, curator of recent fishes, reports on these collections. The scope of this most useful work is, however, much greater than this. Its aim is a comprehensive review of the freshwater fishes of China proper, and it should serve as a handbook to the subject. Outlying territories such as Manchuria and Mongolia are not included. China proper is more or less of a unit faunal area which may be divided into smaller areas and sub-areas. The freshwater fishes are separated into north-central and southern sub-faunas having a standard climatic zonal basis.

Carp-like fishes dominate the Chinese fauna. In a list drawn up by Nichols in 1928, 263 of the 374 species recognized (70 per cent) were carps and loaches (with one sucker) and 11 per cent of the remainder were cat-fishes, so that only 19 per cent belonged to non-ostariophysine groups. Carps are fundamentally non-predacious, feeding on small animals and even on vegetable matter, and are without teeth in the mouth. They have, however, well-developed, variously specialized teeth on the pharyngeal bones (of the throat). In the suckers the pharyngeal teeth are more numerous and arranged in a comb-like series.

The suckers are usually held to be more primitive than, and more or less ancestral to, the carps. One true sucker only is left in China (Myxocyprinus). According to the author one may suppose that the suckers have run their course in China, leaving this peculiar representative behind, and that they have been superseded by the present-day gudgeons, a division of the true carps. The suckers are now almost exclusively North American. This view would make of China a recent centre of differentiation and distribution for carp-like fishes. The true carps are here not only very abundant but also more varied than elsewhere and more advanced in evolution or radial differentiation. Breams, with a single primitive genus in North America and a couple allied to it in Europe, and gudgeons, which seem not to have reached Africa or America but are represented by a few species in Europe, form two sub-families with many genera and species.

Carp-like fishes are the dominant freshwater fishes of the northern hemisphere. Their present distribution is recent, from the north from an Asiatic centre, probably China. The distribution of loaches parallels that of carps. They are probably a secondary offshoot of the true carps. The peculiar Chinese fish Gobiobola combines characters of a loach and of a gudgeon. Catfishes and characins are both older than the carps and probably have invaded their present ranges (South and Middle America and Africa), from the north, where both have been more or less superseded by the carps.

The cultivation of freshwater fishes in China is extensive. Pond-fish culture apparently originated there about 2000 B.C. This doubtless complicates the range of various species and sometimes causes confusion between artificial forms and natural races. The present-day methods are much the same as those in use hundreds of years ago. The fish commonly cultivated are *Cyprinus carpio*, *Labeo jordoni* and species of Hypophthalmichthys. Almost every freshwater fish, large or small, is utilized for food by the Chinese.

In listing the freshwater fishes of China, brief descriptions have been given of the genera and species, with keys to the species when several occur in a genus. Here and there are interesting field notes and descriptions of fishing methods.

There are numerous text-figures, and the nine coloured plates drawn in the field by Mr. Wang Hao-T'ing are admirable.

The well-known Hilsa is the only Clupeoid included in the work. These fishes are marine, occurring along the coasts, but they ascend the rivers to spawn and may penetrate to waters a thousand miles or farther from the sea. An anchovy *Coilia brachygnathus* plays an important part economically, being caught in vast numbers in special nets at Tiengting, Lake Hunan. Of the numerous carps, *Cyprinus carpio* L. is perhaps of the greatest economic importance.

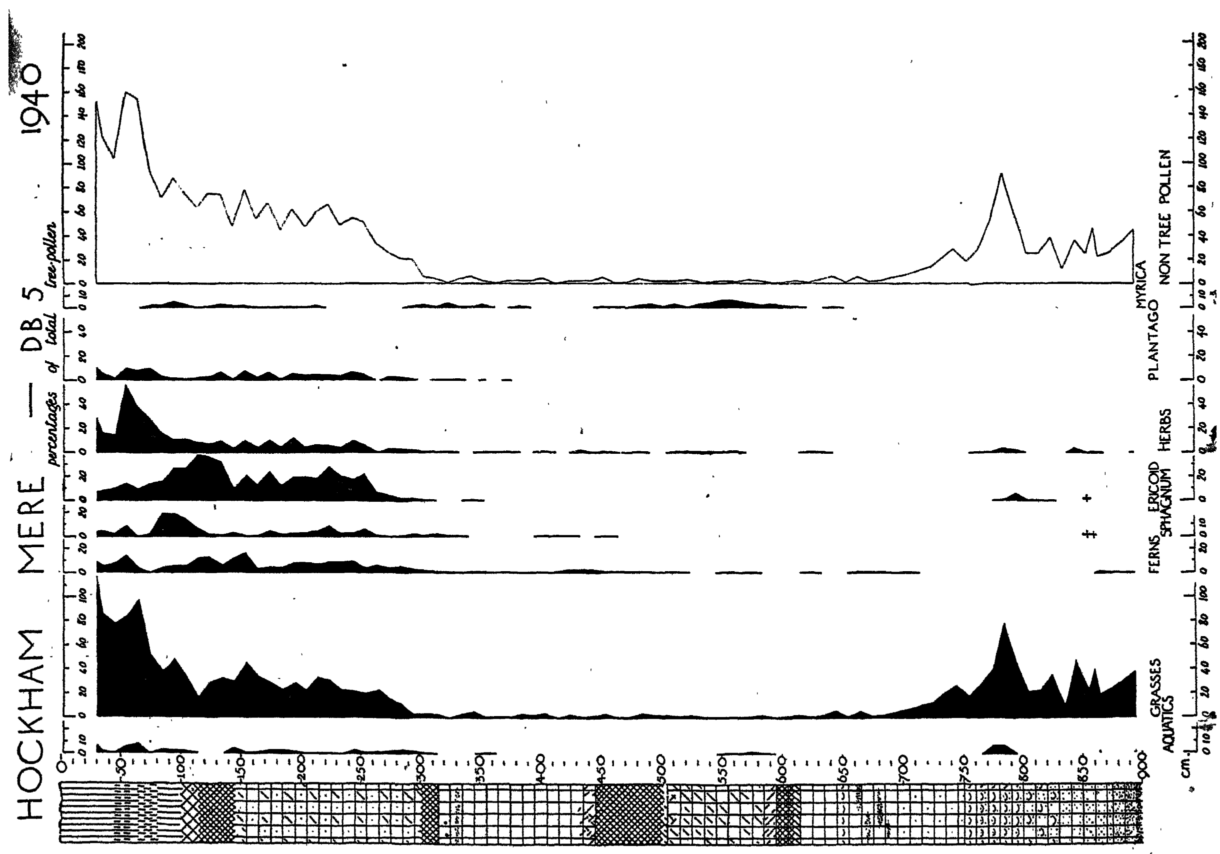
# AGE AND ORIGIN OF THE 'BRECKLAND' HEATHS OF EAST ANGLIA

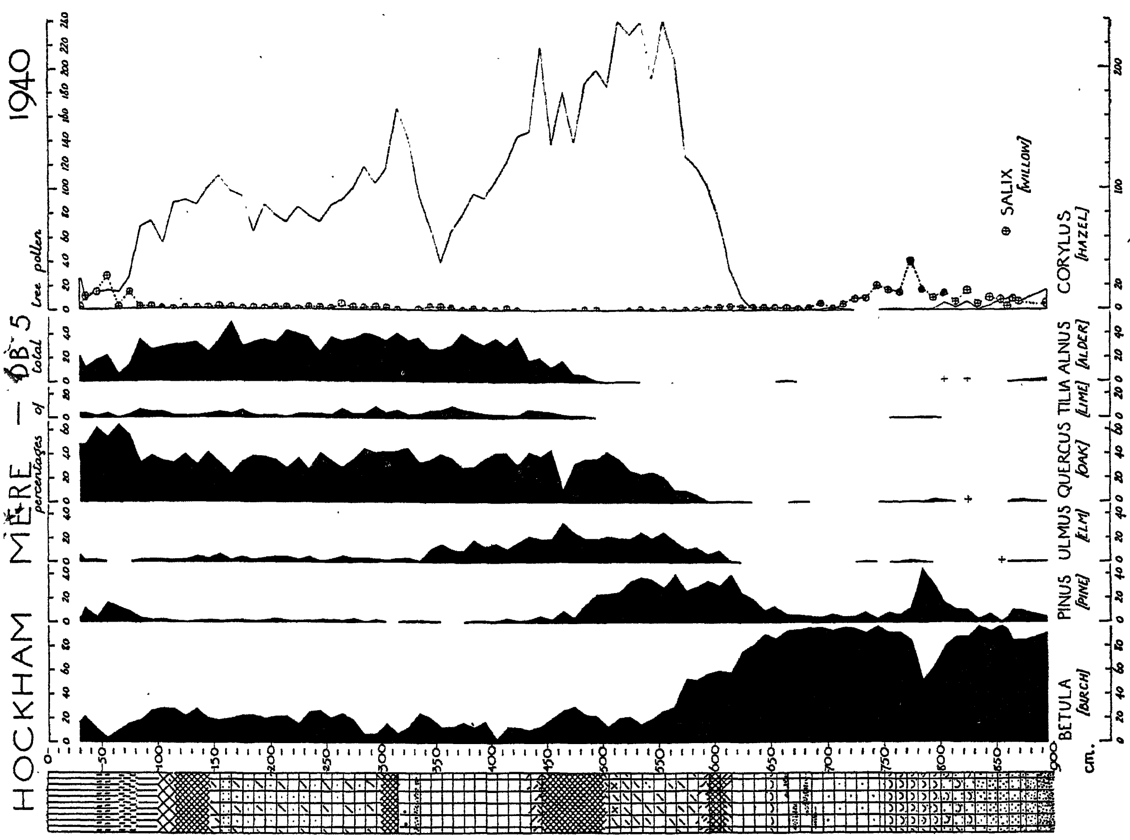
By DR. H. GODWIN
Botany School, Cambridge

IN a recent issue of *Nature*[1] it was pointed out that Iversson had produced evidence from pollen-analysis of lake-muds that, in parts of Denmark colonized by Neolithic man, the continuity and composition of the natural mixed oak forest cover had been much altered by the human introduction of forest clearance by fire. It now seems appropriate to give results which point in a similar direction for the great heath-land area of East Anglia known as the 'Breckland'. The ecological status of the varied plant-communities of grass-heath, sand-sedge, bracken, ling, and sparse woodland has long been in dispute, especially as regards their relation to the factors of climatic, biotic and edaphic (soil) control. It has sometimes been suggested that the rainfall and porous soil may in themselves prevent the development of natural woodland; but others have regarded the heavy grazing, formerly by sheep and now by rabbits, as the only factor preventing recolonization of the heaths by woodland. The basal question has remained unanswered, whether this heathland is determined as such by natural factors, or whether it represents the effect of human interference upon native woodland.

Towards the northern edge of the Breckland is the site of Hockham Mere, which was drained at some unknown post-Tudor date, and the quaking surface of which is now overgrown by wet fen-wood. Borings show that the centre of the lake-basin contains organic lake-muds (nekron-mud or gyttja) to a depth of at least 9 m.: only near the surface are these replaced by the sedge-peats which represent the latest stages of the lake's infilling. Though at the sides the lake-deposits were interrupted, in the lake-centre nekron-mud formed continuously: it is a translucent or rather chalky green jelly with conchoidal fracture, and very rich in pollen. Since such muds form slowly and collect pollen from a wide neighbourhood, it is clear that in the Hockham lake-muds we may expect to find recorded, through the pollen-content, the vegetational history of the northern Breckland throughout a very long period. Moreover, the pollen investigation itself here fulfils a double function. On one hand, the drift of the tree-pollen curves establishes the course of post-glacial forest history, and so allows us to date each stage of the mud accumulation by the correlations already made in Britain between stages of forest-history and archæological, climatic and geological horizons. On the other hand, both tree and non-tree pollen will be direct indexes of the kind of vegetation covering the Breckland hereabouts at each stage of its history.

Events have fortunately realized these possibilities. The tree pollen curves indicate that the oldest muds were formed in a period of birch predominance, where the abundant willow pollen and the high ratio of non-tree to tree pollen indicate the stage of open birch woodland typical of the late-





glacial period. Then follows a relative diminution of the non-tree pollen, and the extension, first of pine and hazel, secondly of elm and oak, and thirdly of lime and alder. The alder-mixed oak forest replaces the birch and pine at a very clear horizon, just as everywhere else in Britain. From this time onwards the tree-pollen curves pursue an uneventful course to the top of the lake deposits, except that we can recognize at 3·3 m. a subsidiary horizon especially indicated by diminution of the elm. This horizon in the Fenland of East Anglia and in the Somerset Levels seems to fall at the opening of the Neolithic period of human culture, and it has been shown to have this correlation also in Denmark and southern Sweden. This correlation is of great importance in the Hockham pollen diagrams, for below this horizon the non-tree pollen of all kinds is negligible; above it there is a sharp increase, and high values of grass-pollen, fern-spores, sphagnum moss spores, ericoid pollen and miscellaneous herb-pollen prevail up to the surface. The nekron-muds continue well above the Early Neolithic horizon, and the stratigraphy makes it clear that this rise in non-tree pollen cannot be due to local changes in the vegetation fringing or filling the lake.

There seems every reason for regarding these high values of non-tree pollens as witness of origin of the Breckland heaths from a pre-existing vegetation of closed mixed oak forest. The high grass-pollen values speak for themselves; the ericoid pollen is indicative of the Calluneta; the fern-spores may or may not have come from bracken communities, for they no longer have their epispores by which fern genera and species can be recognized. The presence of abundant Sphagnum spores is more surprising, but Sphagna persist abundantly in some parts of the Breckland still, and may formerly have been more prevalent. We have not attempted the separate estimation of sedge pollen.

There is no direct evidence of the mechanism by which the vegetational change to heath was brought about; but in view of the conclusions reached by Iversson the correlation of this change with the Neolithic period must be noted, for of course at this time the important flint mines at Grime's Graves were operating, and there is reason to think that there was considerable colonization of Breckland at this time. The suggestion that in a general way the heaths had their origin in Neolithic forest clearance is supported by the recognition that in the Hockham profile, as in Denmark, at the Neolithic level there appears a continuous curve of the pollen of the rib-wort plantain (*Plantago lanceolata*), a species one can only associate with low and relatively open vegetation, and certainly not with woodland cover. It seems likely that with careful diagnosis other equally characteristic species may be identified.

It is pleasing to be able to add in conclusion that Dr. A. S. Watt, speaking from his very extensive knowledge of the ecology of Breckland, sees nothing in this hypothesis of the origin of the Breckland heaths which is not in accord with his own views and experience.

# MAGNETISM IN THEORY AND PRACTICE*

By PROF. EDMUND C. STONER, F.R.S.
University of Leeds

THE central theme of this Kelvin Lecture is that general theoretical explanation of the properties of ferromagnetic materials which has become possible only through those fundamental advances in theory, and by experiment, which have been made since Kelvin's time. This theme cannot, therefore, be so directly linked with Kelvin's work as could that of many previous lectures in the series; but the general field of magnetism is one to which he made extensive contributions on both the mathematical and the applied sides. Moreover, there is a characteristic of Kelvin which is particularly relevant. He combined with his interest in abstract theory an equal interest in practical application, and his achievement bears witness to the value of that combination. Such interests are seldom combined in like degree in one person, certainly not accompanied by corresponding powers and knowledge; but much may be done by finding common ground between those whose main interests and points of view are apparently diverse. This lecture is concerned with a common ground where theory and practice in magnetism meet in connexion with the magnetic properties of materials.

Magnetism in practice, that is as applied for directly useful purposes, is almost exclusively concerned with ferromagnetic materials—with iron, cobalt and nickel, with alloys containing one or more of these metals, and with a few compounds. By theory in connexion with magnetism should be understood that general scheme of ideas and principles, built up from and constantly checked by experiment, in terms of which an explanation is sought of even such complicated observable facts as the properties of ferromagnetics. The aim of theory is to explain. To reach even partial understanding may be a not unworthy end in itself. In addition to this, however, theory may serve as a guide to practice. New theoretical knowledge may not immediately benefit old trades; but a stage is always reached, with the development of theoretical understanding, at which the practical man who despises theory is left far behind the wiser but no less practical man who is alive to the possible bearing of theoretical ideas on his own particular problems. This stage is one which is now perhaps being reached in connexion with magnetic materials.

## Magnetization Curves

The most convenient, though not the most logical, approach to ferromagnetism is through the well-known magnetization curves ($B,H$ or $I,H$ curves) for typical ferromagnetic materials. It is sufficient to recall here, first, that a saturation value of the magnetization is closely approached in moderate fields (seldom more than a few hundred oersteds, and often very much less) and, secondly, that in lower fields the magnetic response to a change of field by a given ferromagnetic depends not only on its state of magnetization, or even on the magnetization and the field, but also on how that state has been reached, that is, on the previous magnetic history of the specimen. This means that the same state of magnetization for the material in bulk, as ordinarily measured, may correspond to widely different distributions of magnetization on a microscopic or submicroscopic scale.

If a comparison is made of the $B,H$ curves for two specimens of material of the same composition which have been differently treated, say mild steel as cast and after annealing, an important point is brought out at once. The low-field characteristics (including the initial and maximum permeabilities, and the coercivity) may be widely different, but the saturation magnetization is the same. The saturation magnetization may be described as a primary characteristic of the material; the low-field behaviour depends on secondary effects. Although the details of this low-field behaviour are of paramount importance in most applications, they can be almost ignored in seeking an explanation of the essential property of a ferromagnetic, which is that it becomes magnetized to a high value, characteristic of the material, in what are effectively still quite small fields. It is necessary to discuss this first, because without some idea of how this high magnetization can come about at all, it is impossible to gain a clear understanding of the low-field properties.

## Elementary Magnets and Intrinsic Magnetization

The changes in magnetization of a material in a magnetic field are ultimately due to slight modifications in the motion of electrons induced by the field or to changes in the orientation distribution of elementary carriers of a magnetic moment. The first effect can be neglected in para- and ferromagnetics. The magnetic moment of a carrier is a resultant of the moments due to the orbital motion and to the spin of electrons forming part of the carrier. In most materials containing elementary carriers of a magnetic moment (such as the metallic ions in a paramagnetic salt) the degree of alignment of the elementary magnets, and hence the magnetization, produced by ordinary fields at ordinary temperatures is very small. In fields of, say, 10 oersteds, the magnetization of a paramagnetic is usually less than that of a ferromagnetic by a factor of the order of $10^5$. From the susceptibility of paramagnetics, the magnetic moment of the elementary carriers can easily be calculated, using the results of a simple statistical treatment. The form of the magnetization curves for ferromagnetics suggests, correctly, that the carriers are aligned nearly parallel in relatively small fields. The magnetic moments per atom of the ferromagnetic metals are, however, of the same order of magnitude as those of the ions of paramagnetic salts.

The attainment of a high degree of magnetization in relatively weak fields by ferromagnetics can only mean that there are, in effect, strong forces tending to align the elementary magnets other than those due to the applied magnetic field. If there were no such forces, fields of the order of several million oersteds would be required to produce the observed magnetization. The forces are not simply magnetic forces between the atomic magnets, which are hundreds of times too small. It was suggested by Weiss, in 1907, that there were forces giving rise to what he called a 'molecular field', proportional to the intensity of magnetization. The development of the consequences of this simple formal assumption led to a remarkable co-ordination of a wide range of ferromagnetic pro-

* Abridgement of the thirty-fifth Kelvin Lecture, delivered before the Institution of Electrical Engineers on April 27.

perties; but no explanation could be given then of how such a field could arise.

It may easily be shown that a substance in which there is a positive molecular field in the Weiss sense would be spontaneously magnetized below a critical temperature (to be identified with the Curie temperature), that is, magnetized even in the absence of an applied field; and that the variation with temperature of the spontaneous magnetization would be similar, at least qualitatively, to that observed for the saturation magnetization. The spontaneous magnetization need not, however, be uniform in direction over an ordinary piece of the material. A piece of a ferromagnetic which appears to be unmagnetized must be fully magnetized to the degree appropriate to the temperature; but the direction of magnetization may vary from one part to another of even a single crystal grain. The regions over which the magnetization is unidirectional, containing perhaps many millions of atoms, are usually known as 'domains'. The process of magnetization by an applied field consists essentially in lining up the directions of magnetization of the individual domains, rather than in changing the numerical magnitude of the already existing magnetization. The fields necessary to align the directions of magnetization of the domains are very much smaller than those which would be required to align the elementary magnets in a domain; but these last fields are, in effect, supplied automatically owing to some special type of interaction between the elementary magnets.

Experiments on the gyromagnetic effect show, almost directly, that the elementary magnets in ferromagnetic metals are electron spins, for which there is ample confirmatory evidence. The electrons involved, which belong to specifiable groups in the free atoms, may be regarded as shared in the metal formed by the aggregation of the atoms. The first step in explaining the molecular field effects is due to Heisenberg, who showed, in 1927, that they could arise from quantum mechanical interchange interaction of the same type as is involved in the explanation of the formation of homopolar molecules of the hydrogen type; but whereas in hydrogen the electron spins point in opposite directions and balance each other magnetically, in a ferromagnetic the spins tend to become aligned parallel to each other. It is clear now why the interaction effect should work this way round for only a limited number of metals; and with sufficient strength to produce ferromagnetism in elements—probably only in iron, cobalt and nickel and in some of the rare earth metals. In detail, however, the theory is still far from being quantitatively worked out.

## The Process of Magnetization

Any piece of a ferromagnetic material must be regarded as made up of domains which are themselves magnetized to the saturation value at the particular temperature. The magnetization as ordinarily measured is a resultant, depending on the orientation distribution of the directions of magnetization of the domains, and on their sizes. There are essentially two types of elementary process by which the magnetization can change: first, by a change in the orientation of the direction of magnetization of a domain (without change of size), and secondly, by a 'growth' of a domain at the expense of others with different directions of magnetization (involving a cumulative re-orientation of electron spins at the moving boundary of the domain). Usually the first type of process predominates on the upper part of a magnetization curve, the second on the initial and steep parts.

The factors controlling the direction of magnetization of an individual domain, apart from the applied field and the magnetization of the remainder of the material, are crystal anisotropy, and strain, due either to externally applied, or local internal stresses. The two effects are of the same kind, for a strain may be regarded as a modification of the symmetry of the atomic arrangement characteristic of the undistorted crystal. The extensive complex of relevant experimental material on the magnetization of single crystals, on magnetostriction of single crystal and ordinary polycrystalline material, and on the effects of external stress (particularly tension) on the magnetization curves, has now been successfully reduced to order. For the present purpose it will be sufficient to state that owing to crystal anisotropy and strain, the energy associated with magnetization depends on the direction of magnetization in a definite and determinate manner. For an unstrained crystal of iron (body centred cubic), for example, the energy is lowest for magnetization along any of the six equivalent cube edge directions. As the field is increased from zero with a polycrystalline specimen (or along an arbitrary direction with a single crystal) the domain directions of magnetization first take up, as a result of boundary displacement processes in comparatively small fields, the cube edge directions which are nearest to the field. Further increase of magnetization then occurs more slowly with increase of field, the magnetization 'rotating' from the cube edge towards the field direction; in this process the magneto-crystalline energy increases and the energy in the field decreases, and for each value of the field an equilibrium direction is taken up. If an applied or local stress is sufficiently large, the strain anisotropy may become more important than the natural crystal anisotropy. Under sufficient tension, for example, a material of negative magnetostriction (such as nickel) acquires an 'easy' direction of magnetization at right angles to the direction of tension, one of positive magnetostriction along that direction, and the forms of the magnetization curves are correspondingly modified. In general, in the demagnetized state, each of the domains of a ferromagnetic is magnetized along one of the easy directions determined by the local crystal orientation and the local strain.

Usually a considerable fraction of the total change of magnetization from zero to saturation occurs by boundary movements (equivalent, in effect, to a partial or complete change of orientation of the domain magnetization by a large angle, such as 90° or 180°, from one easy direction to another) in fields smaller than those required to produce appreciable changes by the reversible rotation process. Domain boundaries may be set up where there are local fluctuations of strain favouring different directions of magnetization in contiguous regions. With an applied field increasing from zero a boundary moves in a direction corresponding to an increase in volume of the domain magnetized with the greatest resultant intensity in the field direction. The movement is at first reversible, the boundary taking up an equilibrium position corresponding to minimum energy for each value of the field. Even with a smooth variation with boundary position of the magneto-elastic energy, at a critical value of the field an unstable position may be reached from which a further

finite movement of the boundary takes place spontaneously (that is, without further increase of field) to a new position of equilibrium.

It is owing to these finite spontaneous boundary movements (corresponding to successive reversals, or finite changes of orientation, as the boundary moves, of electron spins over the greater part of the volume of individual domains) that bulk magnetization may change discontinuously, at least on a microscopic scale, as the field changes continuously. This discontinuous character of magnetization is manifested in the Barkhausen effect. A search coil is placed round a ferromagnetic wire, and connected through an amplifier to headphones. On varying the field continuously (say by bringing up a magnet) a rustling is heard. This rustling is effectively a succession of clicks, each click being due to a sudden change of induction over a finite volume of the material, associated with the change of orientation of electron spins. By an elaboration of the experimental arrangements the size of these volumes (effectively domains) may be determined.

The work of Bozorth and others indicates that most of the change of magnetization on the steep parts of the magnetization curve is due to reversals of groups of electron spins over volumes containing not less than $10^{10}$ atoms. The average size of these volumes varies over the hysteresis loop, the maximum for different materials ranging from about $10^{-9}$ to $5 \times 10^{-8}$ cm.$^3$ (roughly $10^{15}$ atoms) for different materials. Owing to this and other work, domains are no longer to be regarded as vague hypothetical entities, but as having accurately determinable physical characteristics.

The peculiar microscopic distribution of magnetization in ferromagnetics arises from the complex interplay of a number of factors. The interchange interaction, or molecular field effect, very powerful over short distances, tends to align the electron spins parallel to each other. The long-range ordinary magnetic forces tend to produce a state of the ferromagnetic specimen in which there are no free poles, a demagnetized state. The compromise is an arrangement in which there is parallel alignment within each domain, and in which the increase of interaction energy due to the non-parallel alignment in the transition zones, or boundaries, is balanced by the decrease in the purely magnetic energy. The details of the arrangement, such as the precise size of the domains and the width of the boundaries, depend very largely on the magnitude and distribution of the internal strains, that is, on a secondary structure which is not peculiar to ferromagnetics.

The details of the internal stress distribution are dependent not only on mechanical and thermal treatment but also on the presence of atoms or groups of atoms which do not fit smoothly into the main lattice, or in other words do not form a solid solution. These may be impurity atoms which it is difficult to remove, and even in minute amounts their effect in decreasing permeability and increasing coercivity and hysteresis loss may be considerable owing to the local strains introduced. Effects which are disadvantageous if the object is the production of material of high permeability may, however, be aimed at deliberately in the production of alloys of high coercivity suitable for permanent magnets.

Quantitative theoretical expressions have been derived for the initial permeability and the coercivity for a variety of assumed distributions of the internal stress. These all indicate that the initial permeability will vary as the square of the saturation magnetization, $I_0$, and inversely as the product of the saturation magnetostriction, $\lambda$, and the mean amplitude, $Z_i$, of the internal stress variations. The numerical factors are different, but of the same order of magnitude, in different special cases. The coercivity varies directly as the product $\lambda Z_i$ and inversely as $I_0$, but the numerical factor varies over a wide range for different types of stress distribution.

For a full account of the theoretical treatment which has been outlined, and to which many have contributed, reference may be made to the book by Becker and Döring published just before the War. The theoretical ideas not only provide a satisfactory qualitative interpretation of, and guide to, the behaviour of ferromagnetics in low fields, but also, as quantitatively developed, have been experimentally verified in a large number of cases in which the conditions are sufficiently simple and well defined. It should be made clear, however, that as yet it is seldom possible to give a fully quantitative interpretation of the details of the behaviour of particular ferromagnetic materials, the internal structure of which may be extremely complex.

## Magnetic Materials

The suitability of magnetic materials for practical application depends on their mechanical and electrical properties, and on their cost, as well as on their purely magnetic properties. It is obviously not possible to consider here even the more extensively used commercial materials in detail. The bearing of the general discussion may, however, be indicated. The materials used fall into three main types: electrical sheet steels, used for large transformers, and rotating machines; alloys having a high permeability in very low fields, used for loading cables, for transformers and for electrical instruments; and permanent magnet materials.

The requirements of high induction in fields of a few oersteds, low magnetic hysteresis, and low eddy current loss for electrical sheet are to a large extent met by the commercial iron silicon alloys with up to about 5 per cent silicon. The theoretical arguments indicate that magnetic hysteresis loss is largely dependent on internal strains. Various factors contribute to the possibility of minimizing these in the silicon steels. The alloys are single phase; the silicon by a chemical action renders oxygen and carbon impurities less harmful; and material of relatively large grain size may be produced, with a reduction in the strains associated with grain boundaries. The electrical resistivity increases rapidly with silicon content, being about four times that of iron for the 4 per cent alloy, while the reduction in the saturation magnetization for this same alloy is only about 10 per cent. Single crystals of the alloy show the same type of anisotropy as pure iron, having easy directions of magnetization along the cube edges; and for some purposes the properties of the polycrystalline sheet material may be improved by a combination of rolling and heat treatment which produces a preferential orientation of the grains.

Most of the commercial high permeability alloys contain iron and nickel as the main components. In the prototype binary alloys in the iron-nickel series the highest initial permeability is developed, by suitable heat treatment, in the alloy with 78·5 per cent nickel. The theoretical treatment indicates that high initial permeability should be attainable with materials of low magnetostriction. It is a striking

fact that the highest value is found near the composition at which the magnetostriction changes through zero from positive to negative, though factors other than low magnetostriction are undoubtedly involved in the full explanation of the facts. Owing to the low maximum induction of the 78·5 permalloy, alloys of higher iron content are sometimes advantageous. There is a wide series of commercial alloys in which other elements are added to the basic iron–nickel alloy, giving improvements, for certain purposes, in mechanical and electrical and also magnetic properties.

In permanent magnet materials a high remanence is required combined with high coercivity, the best single number criterion of the suitability of the material being the maximum value of the product of $B$ and $H$ on the descending part of the hysteresis curve. Of the innumerable materials which might be used for permanent magnets—there were well over seven hundred patent specifications by 1935—reference will be made only to the recent alloys of which the prototype is a ternary iron–nickel–aluminium alloy of approximate composition represented by $Fe_2NiAl$. With alloys of the general class, values of $(BH)_{max.}$ from three to fifteen times as great as for tungsten steel have been obtained. These alloys exist in a single-phase state at high temperatures, but if slowly cooled they form a heterogeneous mixture of two phases (one of which is usually strongly ferromagnetic compared with the other) at low temperatures. If the cooling is very rapid the single-phase state persists and the coercivity is low. It is also low with very slow cooling when there is a complete segregation of the two phases. For intermediate rates—cooling in air is suitable for some of these alloys—only incipient precipitation occurs. It is then that the high coercivity properties are developed.

In a qualitative way this is in agreement with the theoretical treatment of the dependence of coercivity on the distribution of internal strains. But it would be misleading to give the impression that a complete quantitative explanation of the magnetic properties of these alloys has been given in terms of strains. Moreover, the remarkable improvement in the characteristics of some of these permanent magnet materials by a treatment which includes cooling in a magnetic field is not yet satisfactorily explained. It would perhaps be just a little disappointing if even now all the peculiarities of permanent magnet materials could too easily be completely explained when, for those curious in such matters, the permanent magnet has for so long presented an outstanding problem.

## Conclusion

In the last twenty years immense progress has been made in the understanding of the properties of ferromagnetic materials, largely as a consequence of advances in fields apparently remote from useful practical application—in the investigation of the fine structure of spectral lines, for example, and in the development of quantum mechanics. Some of the outstanding, or incompletely solved problems are inevitably of specialized interest, but others are very wide in their bearing. The question, "How is it that some metals are ferromagnetic ?", is a general question about the metallic state. The investigation of the markedly structure-sensitive low-field magnetic properties may throw light on structure-sensitive properties generally, hardness, plasticity and the like, which are little understood but of central importance in the technology of metals and alloys.

It is proper that users and makers of magnetic materials should know something of what is happening inside a ferromagnetic when it is magnetized, something of the interpretative scheme in which wider theoretical ideas are brought to bear on the characteristics of particular materials. The answer to eminently practical questions about the core losses of transformers may involve reference to electron spins and quantum mechanical interchange interaction. For dealing with the general situation which is exemplified, it is often suggested that there should be much closer collaboration between those concerned with practical problems in industry, and those concerned with theoretical ones in universities. This is indeed most desirable, and the possibility of such collaboration would be welcomed from the academic side; but unfortunately the number of those in universities whose normal duties leave them opportunity for really effective collaboration is minute.

Even if the obvious needs of universities in respect of staffing are met in the future, it would seem desirable that many more young men with the necessary ability and interest for approaching particular problems from a wider theoretical point of view should be given opportunity and encouragement for dealing with them in this way in industry, while keeping in close touch with practical needs. In the field which has been surveyed, a wider permeation of practice by theory would undoubtedly be to the advantage of both.

# NEWS and VIEWS

## University of Liverpool: Prof. P. M. Roxby

FROM Bromsgrove School, Prof. P. M. Roxby entered Christchurch, Oxford, took the History Schools, studied geography under Herbertson, and, in 1906, began his life-work at the University of Liverpool which then inaugurated a Department of Geography. The value of his work for civic and international goodwill was recognized by the endowment, for him, of the Rankine chair of geography at Liverpool. He has therefore served the University of Liverpool for thirty-eight years, for twenty-seven of which he has held the chair so devotedly that no offer could move him away, until now, on the eve of his retirement, he has felt the call to a new and arduous task. He has made the promotion of international understanding the main aim of his work, has exerted a lasting influence on the teaching of geography to this end in the universities and schools of England, Egypt and China, in all of which countries his old students carry on his work.

An Albert Kahn fellowship took Prof. Roxby in 1912 around the world, and he began his studies of Chinese life and problems, which he has broadened by subsequent visits that have made him an acknowledged and most sympathetic interpreter of China to the West. Endless societies, summer schools, conferences and committees for the promotion of international

goodwill have had his generous help with counsel and speech regardless of time or trouble. Students from foreign lands, especially perhaps China and Egypt, have been drawn to his school of geography and have found in him, as have all his students, not only a teacher but also a friend. Now Prof. Roxby is to go to Chungking at the invitation of the British Council to be a chief cultural link between China and Britain. He thus crowns a life's work at the University of Liverpool with a high adventure of goodwill.

## Royal Institute of Chemistry : Retirement of Mr. R. B. Pilcher, O.B.E.

THE recent announcement of the approaching retirement of Mr. R. B. Pilcher from the office of registrar and secretary of the Royal Institute of Chemistry will have been received with much regret by all members and friends of the Institute. Mr. Pilcher joined the staff of the Institute as clerk in 1892, was appointed secretary in 1895 and registrar and secretary in 1900, and will thus, on his retirement next year, have completed fifty years service as secretary. To all members Mr. Pilcher's name is inseparable from that of the Institute, and it is to his loyalty, devotion and care that the success of the Institute is largely due. In Mr. Pilcher a sense of the human values is highly developed and his administration of the affairs of the Institute bears the impress of his character and personality. To many chemists he has been a very present help in trouble. As registrar and secretary of the Institute, Mr. Pilcher has become acquainted with, and has gained the esteem of, most of the leading British chemists of the past half-century, and he has, by his gracious manner and personality, established and maintained cordial relations with Government departments and other authorities. Mr. Pilcher has shown much interest in the earlier history of chemistry and has made a large and valuable collection of engravings of alchemists and alchemical apparatus. His lectures on "Alchemists in Art and Literature" and on "A Century of Chemistry : From Boyle to Priestley", published by the Institute, have given pleasure to many. Mr. Pilcher's literary gifts are shown not only in these lectures but also in his book, "The Profession of Chemistry", and in the more important "History of the Institute : 1877–1914". When the time comes, the good wishes of his friends, and they are many, will go with Mr. Pilcher into his retirement.

## Committees on Agricultural Education

THE Minister of Agriculture and Fisheries and the President of the Board of Education have jointly appointed a committee to advise them on all aspects of agricultural education to be provided by local education authorities, and particularly on the educational policy and methods of training to be adopted at farm institutes. The committee, which will be a permanent body, is constituted as follows: Dr. Thomas Loveday, vice-chancellor of the University of Bristol (*chairman*); Mr. F. Barraclough, secretary to the North Riding of Yorkshire Education Committee; Dr. J. Ewing, H.M. inspector of schools; Mrs. F. C. Jenkins, assistant director, Women's Land Army; Mr. C. Bryner Jones, formerly Welsh secretary of the Ministry of Agriculture; Mr. L. R. Missen, director of education for East Suffolk; Mr. A. E. Monks, an organizer of the National Union of Agricultural Workers now serving as labour liaison officer to the Minister; Mr. W. A. Stewart, county agricultural organizer and principal of the Northamptonshire Institute of Agriculture; Dr. G. K. Sutherland, H.M. inspector of schools; Mr. R. A. Ward, chairman of the Development and Education Committee of the National Farmers' Union; Prof. J. A. Scott Watson, Sibthorpian professor of agriculture in the University of Oxford.

The Minister of Agriculture has also appointed a committee to consider the character and extent of the need for higher agricultural education in England and Wales and to make recommendations as to the facilities which should be provided to meet the need. This committee will deal with agricultural education provided by agricultural colleges and university departments of agriculture, and will take over the functions of the Ministry's war-time Committee on Higher Agricultural Education. The committee consists of Dr. Thomas Loveday (*chairman*); Mr. R. Beloe, chief education officer for Surrey; Mr. D. G. Brown, farmer and member of the war-time Committee on Higher Agricultural Education, member of the Agricultural Improvement Council; Mr. George Brown, an agricultural organizer of the Transport and General Workers' Union and member of the Hertfordshire War Agricultural Executive Committee; Dr. Charles Crowther, principal of Harper Adams Agricultural College and acting director of the National Institute of Poultry Husbandry; Sir Frank Engledow, professor of agriculture in the University of Cambridge, member of the Agricultural Research Council; Mr. C. Bryner Jones (also a member of the Joint Committee); Mr. T. Neame, horticulturist, governor of Wye College, member of Kent Agricultural Education Committee; Prof. E. J. Salisbury, director of the Royal Botanic Gardens, Kew, member of the Agricultural Research Council and of the University Grants Committee; Dr. G. K. Sutherland (also a member of the Joint Committee); Miss D. S. Tomkinson, member of the Worcestershire County Council and chairman of the Agricultural Sub-Committee of the National Federation of Women's Institutes; Mr. L. G. Troup, county agricultural organizer for Hampshire and executive officer of the County War Agricultural Executive Committee; Mr. J. Turner, vice-president of the National Farmers' Union.

The secretary of both Committees is Mr. F. L. Wormald, Ministry of Agriculture and Fisheries, Block 4, Bickenhall Mansions, Baker Street, W.1.

## Artificial Insemination of Cattle

THE Minister of Agriculture and Fisheries has recently arranged for a review of the principles on which the development of artificial insemination centres in England and Wales should be planned and controlled. Discussions have taken place with the National Cattle Breeders' Association, the National Farmers' Union and the Milk Marketing Board. It is considered that artificial insemination centres should be controlled and developed as a national service on behalf of the livestock industry and that, with the exception of centres established for experimental purposes, licences for such centres should be granted in future only to organizations controlled and financed by producers, such as the Milk Marketing Board, farmers' co-operative societies and the cattle breed societies. It would be a condition of the licence that the centre would be available to all producers of cattle within the area of operation. A Central Advisory Committee is being appointed to advise the Minister upon the economic aspects of the control

and development of centres and to consider applications for licences to set up such centres. The chairman and eight members are being appointed by the Minister, and four members each by the Milk Marketing Board, the National Farmers' Union, and collectively by the cattle breed societies.

## Therapeutic Trials Committee

VOL. 2, Nos. 3 and 4 of the *British Medical Bulletin* is devoted to certain drugs and their modes of action. Dr. F. H. K. Green, of the administrative staff of the Medical Research Council, describes the work of that Council's Therapeutic Trials Committee. In response to representations by the Association of Chemical Manufacturers, the Medical Research Council organized in 1931 a scheme for the clinical testing of new remedies, and the Therapeutic Trials Committee was set up as a disinterested intermediary between the manufacturers and the medical profession, some medical men having been reluctant to carry out tests at the request of commercial firms. It was agreed that foreign as well as British remedies should be tried out and also the products of academic as well as of commercial laboratories. Manufacturers desiring trials by the Medical Research Council must agree to certain conditions. The composition and nature of the substance to be tested must be fully revealed to the Council; manufacturers must not, without the Council's permission, arrange for other independent trials, and the Council is interested only in new substances which have not been therapeutically tested.

When a substance is to be tested, arrangements are made with clinicians of high standing to make tests, usually at more than one hospital, and the Council reserves the right to decide whether the results, favourable or not, shall be published or revealed only to the manufacturer. If a clinician's results are published, they are published under the clinician's name as a report to the Therapeutic Trials Committee. Since the scheme was organized in 1931, more than forty new substances have been tested clinically. Outstanding examples are the classical papers embodying the results of clinical trials of 'prontosil rubrum', which established the therapeutic possibilities in man of the first sulphonamide drug, which had been discovered in Germany; some of the earliest controlled clinical tests of sulphanilamide; trials of stilbœstrol and other synthetic œstrogenic agents. During the War clinical tests of penicillin have been organized and are still going on, and British-made equivalents of important foreign pharmaceutical products are being tested. The control of infections of wounds and burns is also being studied. Ultimately, says Dr. Green, it is at the bedside that the clinical value of any new remedy is decided; but it is evident that the manufacturer, the medical man and the patient all stand to gain by the excellent work of the Therapeutic Trials Committee.

## The Ray Society

THE Ray Society was constituted at a meeting held on February 2, 1844. The report of the Council for the year 1943, which has just been circulated, states that it had been hoped to mark the centenary year by publishing a record of the Society's history; but the preparation of this had to be postponed until libraries are more accessible and times more favourable. It is regretted that it has not been possible to issue any publications during the year, the lamented death of Prof. W. M. Tattersall having prevented the completion of his volume on the British Mysidacea, which, however, is now being prepared for printing by Mrs. Tattersall. A work by Dr. F. E. Zeuner on "The Pleistocene Period, its Chronology, Climate and Faunal Successions" is now in the hands of the printers. The Society has not hitherto published any works dealing primarily with geology, but the Council considers that the subject-matter of Dr. Zeuner's book is so intimately connected with questions relating to the origin and distribution of the existing fauna and flora that it will be of great interest to many members of the Society. Reference is made to the loss suffered by the Society in the death of Sir David Prain, who had rendered important and long-continued service as a member of Council, as treasurer (1932–37), as a vice-president and as a trustee for the Society's investments. The annual general meeting for the current year having been omitted with the consent of the members, the present officers and Council will continue in office.

## Sensitivity of the Human Eye

DR. SELIG HECHT, professor of biophysics at Columbia University, has recently made a tour of American colleges and universities, during which he has lectured to fifteen different Chapters of the Society of the Sigma Xi. His lecture gave some interesting data, arising from his own researches, on the sensitivity of the eye. Under the most favourable conditions, the smallest amount of light which the human eye can detect is 58–148 quanta, representing an energy of $2–6 \times 10^{-10}$ ergs. This 58–148 quanta is the amount of light falling on the cornea, but only about 10 per cent (5–14 quanta) of this is actually absorbed by the retina; the rest is lost by corneal reflexion (4 per cent), absorption by ocular media (50 per cent) and passing on beyond the retina (36 per cent). In the particular experiments described, this 5–14 quanta were absorbed by an area of retina which contained about five hundred receptor cells (rods). It seems reasonable to suppose, therefore, that each quantum was absorbed by a separate receptor cell. Chemical studies have shown that one quantum of light changes (bleaches) one molecule of visual purple. The conclusion reached is that we can see a light when the energy from it is sufficient to bleach one molecule of visual purple in each of 5–14 separate receptor cells.

## Wood Preservatives and Termite Attacks

IN a recent pamphlet entitled "Effectiveness of Wood Preservatives in Preventing Attack by Termites" (U.S. Dept. of Agriculture. Circ. 683. By T. E. Snyder and J. Zetek. Washington: Gov. Printing Office. 10 cents) the opening paragraphs have a familiar ring to those acquainted with some of the more domestic troubles of early British rule in India and elsewhere in the tropics. "Wood has been classified," says the writer, "in the present global war as a critical structural material. Much of the wood to be utilized for the construction of the large number of necessary barracks and storage depots must be installed in the Tropics. Even in the event of a short War, past experience has shown that structures built to last for only short periods of service must be continued to be used long after the War is over. For the protection of wood from attack considerable research and investigation work

has been carried out for some years by several research organisations in the United States, e.g., Forest Products Laboratory of the U.S. Dept. of Agric.; Chemical Warfare Service of the War Dept.; California Termite Investigations Committee; the Western Union Telegraph Company and others." Various wood preservatives have been experimented with, and the writer of the pamphlet deals with them under three heads. Preservative oils, such as creosotes and combinations in petroleum or tar—especially adapted for penetration of timber to be used in contact with the ground. Water-soluble salts, such as zinc chloride, chromated zinc chloride and several proprietary preservatives, are for use as 'white' or clean pretreatments; they are ordinarily used above ground and the wood can be finished or painted after treatment. Certain toxic chemicals which are nearly colourless, dissolved in light petroleum oils, are adapted for the non-pressure immersion treatment of finished articles. The wood does not swell or shrink, dries rapidly, and is left clean, and after treatment it can be finished or painted. Many methods have now been devised for preserving wood, some simple non-pressure processes, others pressure processes requiring expensive equipment.

## American Philosophical Society

The American Philosophical Society Year Book 1942 covers the year January 1, 1942, to December 31, 1942, and, in addition to the minutes of the meetings and of the executive sessions, includes the reports of standing committees, the report of the Special Committee on Zoology in the Library of the Society, awards of prizes and a list of members. The report of the Committee on the Library refers to the study, in furtherance of the policy of selecting the history of American science and culture as one of the two or three major fields in which the Library should develop its holdings, by a committee of Dr. Conklin, Dr. Moore and the Librarian, of the possibility of building up a really great collection on the history of evolution. The report of the Committee on Research details the general principles adopted in regard to grants, requests for which have been fewer than previously because of the participation of many scientific men in research connected with the war effort. Increased demands are anticipated after the War, and the Committee has recommended accordingly that there should be no reduction in the amount assigned for 1943, but that any unexpended balances in the three funds for 1942 and 1943 should be carried over to be disposed of by the Committee after the War. Lists of grants from the Penrose Fund, the Johnson Fund and the Dorland Fund are included with brief reports from recipients of grants on their work. Obituary notices of members include some which will be of interest to British readers.

## University of Leeds Library

The report of the librarian of the University of Leeds for the session 1942–43 refers to the rapid growth of the Library as shown by the addition of 5,244 volumes during the year, 4,965 of which were added to the Brotherton Library, as well as 2,182 pamphlets and 8,051 periodicals (parts). The total holding of the Library is now 245,839 volumes and 11,007 pamphlets. In the Brotherton Library, 17,476 slips were added to the author catalogue and 2,800 cards to the subject catalogue during the year, figures which are, in all, higher than any previously recorded. Although the inter-lending scheme was originally adopted by the Library Committee with reluctance, it is now generally agreed that the scheme has become of great national importance, and instances are quoted in the report of the lending of publications which proved of inestimable value. No further increase can be coped with in this respect if the staff continues to be depleted without efficient replacement. A thorough overhaul of the medical library has been commenced and extensive purchases made; but the problem of accommodation is more acute than ever. The use of the Holden Library also continues to increase, and when the rare books and series that have been removed from Leeds are returned there will be no more vacant shelf space. In spite of the fact that the rare books and manuscripts of the Brotherton Collection remain in places of safety away from the University, inquiries from outside have increased.

## Repeaters in Submarine Cable Telephony

A paper read in London on May 11 before the Institution of Electrical Engineers by Mr. R. J. Halsay considers the problem of multi-channel carrier telephone working on submarine cables, to the permissible limits of attenuation, in relation to present-day practice, and examines the difficulties thereof. While it will be possible to obtain some small increase in the utilization efficiency of such cables by increasing the transmitted power, reduction of the permissible receiving level below the present limit of about $-110$ db. appears to be impracticable. Development has now reached a stage where the availability of submerged repeaters is essential to further substantial progress, and the design of such repeaters is engaging attention both in Great Britain and in the United States of America. Details of a repeater, laid by the British Post Office in the Irish Sea on June 24, 1943, are given in the paper, and it is believed this repeater is the first to be incorporated in a working cable system. It is suitable for depths down to about 200 fathoms, though at present it is laid in only 35 fathoms. By its use the number of circuits operable over the single cable has been increased from 24 to 48. The further development of repeaters for shallow- and deep-water operation is discussed, the ultimate objective being the provision of considerable numbers of inter-continental telephone circuits over submarine cables.

## Institute of Industrial Administration

The report of the October 1943 conference of the Institute of Industrial Administration has now been issued under the title "Management in Action". It includes papers by W. C. Puckey on "Organising for Production", by E. F. L. Brech on "The Personnel Function", by C. E. Holmstrom on "Marketing the Product", and by A. L. C. Chalk on "Financial Administration", together with Sir Cecil Weir's address "Industry After the War" and the presidential address by Viscount Davidson, and also reports of the discussions. The report emphasizes that the idea underlying all the papers is that management must be, first and last, an instrument of service to the community, and indicates that the Institute is facing the problem of the integration of industry and society as one of the first we must solve if we are to build a post-war social and industrial structure which gives full play to individuality and human values.

## College of the Pharmaceutical Society

THE College of the Pharmaceutical Society of Great Britain has continued in its temporary accommodation in Cardiff, being distributed between University College and the Medical Unit of the Royal Infirmary, with the Pharmacological Laboratories and Department of Nutrition under the direction of Dr. K. H. Coward at the National Institute of Research in Dairying, Reading. The chair of pharmacology, left vacant by the appointment of Prof. J. H. Gaddum to Edinburgh, has not yet been filled. Although the College has lost many of its research workers, who left for some form of national service during 1942–43, it is gratifying to see that a large output of research work is still being maintained, as judged by the "Annual Report of Research Work" covering the period January 1942–June 1943, which has recently been issued.

## Two Czech Chemists

THE Association of Czechoslovak Scientists and Technicians and the Czechoslovak Research Institute, London, have issued a pamphlet with the above title, by Dr. G. Druce (New Europe Publishing Co., 29 St. James's Street, London, S.W.1. Pp. 67. *3s. 6d.*). It describes the life and contributions to science of Prof. Bohuslav Brauner (1855–1935) and the less known Frantisek Wald (1861–1930). An adequate account is given of Brauner's work in inorganic chemistry, which centred around the Periodic Law; and the theoretical views of Wald on stoichiometry and the theory of phases (which were highly rated by Ostwald) are explained in an intelligible way. The work, which has useful bibliographies, is a significant and interesting contribution to the history of chemistry.

## Lady Tata Memorial Trust Awards

THE Trustees of the Lady Tata Memorial Fund announce that, on the recommendation of the Scientific Advisory Committee, they have agreed, if circumstances permit, to make the following awards for research in blood diseases, with special reference to leukæmia, in the academic year beginning on October 1, 1944: grants for research expenses to Prof. L. Doljanski (Jerusalem), Dr. J. Furth (New York), Dr. P. A. Gorer (London), Dr. A. H. T. Robb-Smith (Oxford); part-time personal grant and grant for research expenses to Dr. W. Jacobson (Cambridge).

## University of London

PROF. FRANK HORTON has been re-elected vice-chancellor of the University of London. Recent appointments in the University include the following: Dr. H. B. Acton, lecturer in philosophy at Bedford College, to the University chair of philosophy tenable at Bedford College. Dr. H. T. Flint, reader in physics at King's College, to the Hildred Carlile chair of physics tenable at Bedford College. Dr. W. N. Bailey, lecturer in mathematics in the University of Manchester, to the University chair of mathematics tenable at Bedford College. The title of reader in zoology in the University has been conferred on Mr. G. P. Wells in respect of the post held by him at University College. The degree of D.Sc. has been conferred on E. J. Irons (Queen Mary College), A. G. Quarrell (Imperial College), R. W. Powell and R. H. Common.

The following, among others, have been appointed fellows of King's College: Dr. T. Loveday, vice-chancellor of the University of Bristol; Dr. R. E. Priestley, principal and vice-chancellor of the University of Birmingham; Sir Hector Hetherington, principal and vice-chancellor of the University of Glasgow; and Dr. J. Henderson, sub-dean of the Faculty of Science of the College.

## Summer School in Health Education

IN response to requests from the Ministry of Health and the Board of Education, and in order to reduce the strain on the country's transport system, the Central Council for Health Education has decided not to proceed with its Durham School, and to limit attendance at the London School (August 9–19) to students from London and the Home Counties. Details of the London School may be obtained from the Medical Adviser and Secretary, Central Council for Health Education, Tavistock House, Tavistock Square, London, W.C.1.

## Announcements

DR. H. G. SANDERS, lecturer in agriculture in the University of Cambridge, has been appointed professor of agriculture in the University of Reading, in succession to Prof. R. Rae.

LORD HAILEY has been elected president of the Research Defence Society.

BY authorization of the University Court, the Department of Chemistry in relation to Medicine in the University of Edinburgh, the head of which is Prof. G. F. Marrian, will in future be known as the Department of Biochemistry.

DR. C. J. SMITHELLS has been appointed director of research of the British Aluminium Co., Ltd., and will take up his duties in August next. Dr. Smithells was an original member of the research staff of the General Electric Co., Ltd., which he left in 1938 to become general manager of Lodge Plugs, Ltd. He is the author of several books on metallurgical subjects. Dr. A. G. C. Gwyer, the scientific manager of the British Aluminium Co., will reach the retiring age in October 1945, after thirty-three years' service with the Company. During the intervening period he will remain in a consultative capacity in order to assist Dr. Smithells to become conversant with the many problems arising in the Company's research activities.

THE exhibition "Chemicals in War and Reconstruction" organized by the Association of Scientific Workers, will be on view in the Art Gallery, Huddersfield, during the week July 7–14 between 10 a.m. and 7.30 p.m. It will be opened at 6 p.m. on July 6 by Mr. G. B. Jones, chairman of the Yorkshire Section of the Society of Chemical Industry.

IN connexion with the article "Freedom from Want of Food" in *Nature* of June 17, p. 750, Sir Jack Drummond writes: "I did not say that far more milk is being produced to-day than before the War; I directed attention to the rise in consumption of liquid milk that has occurred since 1939. As shown in a recent Ministry of Food publication: 'Food Consumption Levels in the United States, Canada and the United Kingdom', H.M. Stationery Office, 1944, the consumption of milk products in the United Kingdom, excluding butter, in 1943 was 28 per cent greater than in the years immediately before the war".

# LETTERS TO THE EDITORS

*The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.*

## A Virus Attacking Lettuce and Dandelion

DURING the last three years lettuces have been seen in different parts of Britain suffering from a severe disease, the symptoms suggesting infection with a virus. The cause has now been found to be a virus that is also responsible for the chlorotic rings and spots so commonly seen in dandelion (*Taraxacum officinale*).

Symptoms in lettuce appear 1–2 weeks after infection; the young leaves become bronzed as a result of fine brown necroses that form along the veins and in the interveinal areas. In the glasshouse, this is usually only a primary symptom and is followed by chlorosis, with dwarfing and malformation of the whole plants. In the open, necrosis is the major symptom; whole leaves become black and shrivelled and the plants are worthless. The disease is more severe than the common lettuce mosaic and is readily distinguished from it.

The virus is only transmitted by inoculation if some abrasive, such as carborundum, is incorporated in the inoculum. It has been transmitted by the aphides *Myzus ornatus* Laing and *Myzus pseudosolani* Theob., but not by *Myzus persicæ* Sulz., the vector of lettuce mosaic virus. The behaviour of the insect vectors seems to differ from any previously described. No infections are obtained unless aphides feed for at least three hours on the source of infection, and the number of aphides that become infective increases with increased feeding time. This is characteristic of the viruses called persistent by Watson and Roberts[1], but even after feeding for as long as three days on the source of infection the vectors cease to be infective within an hour.

As the perennial host is likely to be the source of infection for the lettuce crop, the name dandelion yellow mosaic virus is suggested.

## Activation of Pyrethrins by Sesame Oil

IN an article on "Activation of Pyrethrins in Fly-Sprays", David and Bracey[1] state that the test insect used in their work was the mosquito, *Aedes ægypti*, and point out that their findings may not hold for other insects. Nevertheless, the use of the term "fly-sprays" in the title is perhaps unfortunate, for we have found that many of their conclusions drawn from work on Aedes do not hold when the house-fly, *Musca domestica*, is the test insect. As shown below, the substitution of lubricating oil, etc., for sesame oil in fly sprays, or in dual-purpose sprays intended for fly and mosquito control, would be unjustified, since such substances do not increase the toxicity of pyrethrins to flies.

Tests on the house-fly are carried out at the Pest Infestation Laboratory in a glass-fronted wooden chamber of 18 cub. ft. capacity. The insecticide is atomized into the chamber by means of an Aerograph artist's brush Type *AE* supplied with air at 50 cm. free mercury pressure. The flies are reared at 27·5° C. and 55–60 per cent relative humidity, and are kept under these conditions before, during and after test. The flies, four–six days old, are liberated into the chamber before spraying and are exposed to the insecticidal mist for 10 min., after which they are returned to their cage for observation of the percentage kill 24 hr. later. The percentage knock-down is counted during and at the end of the 10-min. exposure period.

Earlier work with seventeen samples of sesame oil of various origins showed that the oils caused markedly different degrees of activation of pyrethrins. One oil (sample *TA*.3) caused a slight reduction in both knock-down and kill when incorporated with pyrethrins. This oil was tested again with three other substances of low volatility with the following results. (All percentage kills are corrected for control deaths.)

| Pyrethrins (% w./v.) | Adjuvant (v./v.) | Av. kill (per cent) |
|---|---|---|
| 0·05 | — | 41·5 |
| 0·05 | 5% sesame oil *TA*.3 | 35·2 |
| 0·05 | 5% oleic acid | 48·2 |
| 0·05 | 5% med. paraffin | 30·6 |
| 0·05 | 5% lubricating oil | 36·2 |

It was concluded that adjuvants of low volatility do not as a general rule increase the toxicity of pyrethrins to house-flies, and that those tested have little or no inherent toxic effect when used at 5 per cent. This experiment gave no significant information upon the rate of knock-down of the flies, so several sprays were tested at a reduced dosage.

| Pyrethrins (% w./v.) | Adjuvant (v./v.) | Av. per cent knock-down at 2 min. | 4 min. | 6 min. | 10 min. |
|---|---|---|---|---|---|
| 0·05 | — | 54·7 | 83·2 | 93·8 | 96·7 |
| 0·05 | 5% sesame oil *TA*.3 | 29·6 | 62·8 | 74·4 | 86·6 |
| 0·05 | 5% sesame oil *TA*.4 | 59·1 | 86·1 | 95·0 | 99·2 |
| 0·05 | 5% med. paraffin | 42·5 | 77·4 | 86·2 | 91·6 |
| 0·05 | 0·05% w./v. sesamin | 60·5 | 87·2 | 95·6 | 99·3 |

Sesame oil *TA*.3 and medicinal paraffin reduced the rate of knock-down. Sesame oil *TA*.4, which in several earlier tests has been shown to cause a marked increase in kill of flies by pyrethrins, produced a small increase in the rate of knock-down, as also did sesamin incorporated at a concentration approximately equivalent to that contained in 5 per cent of *TA*.4. With our method of test using flies, therefore, activation for kill is not dependent upon reduction of the rate of knock-down.

The effect of sesamin on kill is shown by the data below.

| Expt. No. | Pyrethrins (% w./v.) | Adjuvant (v./v.) | Av. kill (per cent) |
|---|---|---|---|
| 72 | 0·05 | 5% sesame oil *TA*.43 | 72·9 |
| 72 | 0·05 | 5% *TA*.43 desesaminized | 53·6 |
| 74 | 0·05 | — | 22·8 |
| 74 | 0·05 | 5% sesame oil *TA*.44 | 48·0 |
| 74 | 0·05 | 5% *TA*.44 desesaminized | 29·7 |
| 73 | 0·05 | — | 36·6 |
| 73 | 0·05 | 0·05% w./v. sesamin | 72·8 |

At the time of these experiments the flies were passing through a period of fluctuating resistance. Nevertheless, the following conclusions are valid because the flies for each experiment were obtained from batches of puparia drawn from randomized popula-

tions. Exp. 72 showed that sesame oil *TA*.43 lost markedly in activating power on removal of the sesamin. The mortality with the desesaminized oil was, however, higher than expected of an oil with no activating power. This result was confirmed in expt. 74, in which 0·05 per cent pyrethrins was included for comparison. Exp. 73 demonstrated clearly the activating effect of sesamin.

Five per cent w./v. of sesame oil *TA*.4 used alone in kerosene has been shown to be insufficiently toxic to flies to account for the increase in kill by pyrethrins observed when *TA*.4 was incorporated in the spray.

From chamber tests on house-flies by the method in use at this laboratory, activation by sesame oil of the toxicity of pyrethrins appears, therefore, to be dependent mainly upon the sesamin content of the oil, and increase in kill is accompanied by a small increase in the rate of knock-down. Medicinal paraffin and sesame oil *TA*.3 reduced both the rate of knock-down and the kill by pyrethrins. With Musca, oleic acid and lubricating oil when mixed with pyrethrins caused little or no increase in kill, in contrast to the data recorded by David and Bracey in their tests on Aedes.

The inactive sample of sesame oil *TA*.3 gave a positive colour reaction for sesamin, and optical measurements indicated a sesamin content of about 0·3 per cent w./v. as against the normal 1 per cent (approx.). We now have, therefore, an oil containing a little sesamin, which reduces slightly the toxicity of pyrethrins to the house-fly, and two samples of desesaminized oils, which give a negative colour reaction for sesamin yet cause a slight increase in the toxicity of pyrethrins. There is no reason to doubt that the constituent of sesame oil chiefly responsible for activation of pyrethrins is sesamin; but it seems that there may also be present a complex of secondary factors which, according to its composition, may increase or decrease the effect of the pyrethrins and/or sesamin in a fly spray.

We wish to acknowledge the co-operation of Mr. B. A. Ellis, Government Laboratory, in this investigation, especially for the provision of samples of sesamin and desesaminized oils.

This note, which is based on work being carried out for the Pest Infestation Research Committee, is published by permission of the Department of Scientific and Industrial Research.

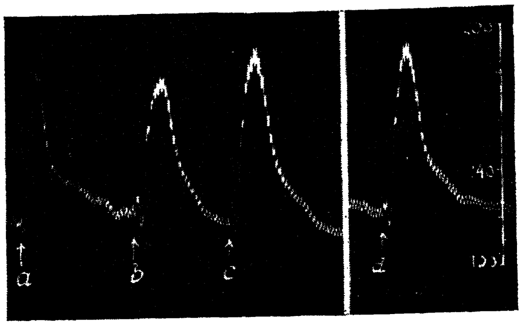
## Identification of a Urine Base with Nicotine-like Action

In a previous communication, the isolation from urine of a volatile base with nicotine-like action has been announced[1]. The active substance was obtained from normal fresh cow's urine by means of continuous fluid extraction with ether, and isolated as picrate. On the assumption that the active base formed picrate and hydrochloride with one equivalent of acid, the molecular weight was estimated to be 80–90. The active compound showed the reactions of a secondary amine. Microanalysis of the crystalline picrate yielded results which would correspond to the formula $C_5H_{11}N$ for the base.



BLOOD-PRESSURE, CAT, CHLORALOSE. HALF AN HOUR PREVIOUSLY THE ANIMAL HAD RECEIVED 0·1 MGM. ERGOTAMINE TARTRATE PER KGM. *i.v.*

(*a*) 0·05 mgm. nicotine; (*b*) 1 mgm. piperidine hydrochloride; (*c*) 1·5 mgm. of same; (*d*) 1·5 mgm. of urine base hydrochloride.

The nicotine-like effect, which in strength was about $\frac{1}{15}-\frac{1}{20}$ of that of nicotine, and the chemical data obtained, made it probable that the substance was closely related to piperidine. The picrate and hydrochloride of piperidine were accordingly prepared and their action compared with those of the picrate and the hydrochloride of the urine base on the blood-pressure of the cat before and after atropine, on the rabbit's isolated intestine, on the isolated uterus of the cat and on the unanæsthetized frog. In all instances the biological actions of the two sets of substances were, weight for weight, identical. The illustration shows the effect on the blood-pressure of the cat.

The picrate of the urine base melted at 142°, the piperidine picrate at 145° and a mixture of both at 142–143°.

The evidence thus obtained, chemical and physiological, seems to justify the conclusion that the active base is piperidine.

As to the origin of piperidine in urine (up to 10 mgm. per litre) no statements can be made at present. Tentatively, its formation from lysine and pentamethylene diamine should be considered.

## Effect of Unsaturated Fatty Acids upon the Growth of *Lactobacillus helveticus* and other Gram-positive Bacteria

The findings of Bauernfeind *et al.*[1] and of Strong and Carpenter[2] suggest that the accuracy of microbiological assays for riboflavin, with *Lactobacillus helveticus* as the test organism, may be seriously affected by the presence of fatty acids in the extracts under investigation. We have studied the conditions under which such interference may occur using a medium freed from lipids by chloroform extraction. Our results will be reported in detail elsewhere[3].

We find that the growth of an American strain of

*L. helveticus* (from Snell and Strong's original strain No. 7469 and kindly supplied by Dr. Barton-Wright) is almost normal on a medium similar to those of Snell and Strong[4,5] and of Barton-Wright *et al.*[6] but twice extracted with chloroform. Growth has been estimated with varying amounts of riboflavin ranging from 0·05 to 0·5 μgm. per 10 ml. of medium, and with a standardized inoculum and test procedure. The addition of 160 μgm. of caproic or caprylic acid per 10 ml. of extracted medium does not interfere with growth, but similar amounts of palmitic or stearic acid augment it. Oleic acid, however, suppresses growth completely over a period of twenty-four hours, but not for longer. Linoleic and linolenic acids are much more active than oleic acid, inhibiting growth completely for seventy-two hours (the test period we adopt as a routine) and indeed for some days. Half the quantity of linoleic and linolenic acids, that is, 80 μgm. per 10 ml. will almost completely inhibit the growth of our standard inoculum (about 400 million bacteria) for forty-eight hours (linolenic acid more than linoleic acid), and will inhibit the growth of an inoculum of 200 million bacteria for the full seventy-two hours. Sodium salts of these unsaturated fatty acids are equally effective, but their methyl esters are inactive.

The inhibiting action of linoleic acid in a chloroform-extracted medium is reversed in a striking manner by a number of compounds, some of which, like linoleic acid, are surface-active. Thus, in a concentration of 160 μgm. per 10 ml., cholesterol, lecithin, lumisterol, calciferol (but not ergosterol), α-tocopherol, and α-tocopherol acetate completely reverse the action of a similar quantity of linoleic acid. A wide range of other compounds, including fatty acids, vitamins, hormones and carcinogens, does not show any reversing action, but stearic acid, œstrone, sodium fumarate, oxaloacetic acid, maleic acid and dihydroxymaleic acid are weakly active in this respect. The reversing action of cholesterol and of lecithin is found to be equally potent even when the cultures have been inhibited for 48 hours by linoleic acid.

The effects of linoleic acid, so far as we have been able to observe, are reproducible in the case of other Gram-positive bacteria, namely, *Streptococcus agalactiæ*, *Staphylococcus albus*, *Bacillus anthracis*, *Listeria monocytogenes* and *Erysipelothrix rhusiopathiæ*, but not in the case of the Gram-negative *Bacterium coli* and *Proteus vulgaris*. The inhibitory action is marked not only in chloroform-extracted medium, but also in unextracted assay medium and in glucose-broth.

Although a dietary essential, linoleic acid appears to be highly toxic when injected parenterally into mice.

## Specificity and Mode of Action of Histamine

WHEN human skin is injured, a substance is released into the tissue spaces which brings about the so-called triple response: a local dilatation of the skin vessels, an increase in their permeability leading to wheal formation, and around this an area of further vasodilatation without notable change in permeability, mediated through a nerve axon reflex. Lewis has shown[1] that when a needle is pricked into the skin through a drop of a dilute solution of a histamine salt, this same triple response occurs, and he therefore suggests that the natural excitant substance ($H$-substance) may also be histamine. We have investigated the chemical specificity of the response in detail by Lewis's simple technique, comparing all results with the negligible effects of control pricks through 0·9 per cent saline.

Table 1 shows that whereas histamine dihydrochloride itself even in $M/10{,}000$ concentration produces a definite response, the compounds of groups $A$, $B$, and $C$ are all inactive, though in much higher concentration. Those of group $D$ gave weak positive responses in the concentrations stated, presumably by liberating $H$-substance. In other words, the skin reaction appears to be highly specific, in a way similar to the action of histamine on other tissues[2], and this may be taken as additional evidence in favour of the view that histamine and the natural $H$-substance are identical.

Current pharmacological theory[3] holds that many drugs may exert their highly specific effects through the action on specific enzymes in the cell interfering with normal metabolic processes. We have, therefore, tested the effect of histamine on the oxygen uptake and aerobic and anaerobic glycolysis of fresh baker's yeast, which is said to contain no histaminase[4], and which resembles muscle and other mammalian tissues in some of its enzyme systems.

From Table 2 it is seen that histamine acid phos-

phate in a final concentration even so high as $M/20$ has no significant effect on respiration and produces only a small but unspecific increase of glycolysis in fresh baker's yeast under our conditions.

The succinic dehydrogenase–cytochrome system was also set up, using succinate, pure cytochrome c, and washed minced heart muscle in phosphate buffer $p$H 7·3, kindly prepared by Dr. Hartree. There was no significant difference in the oxygen uptake measured in Barcroft manometers at 39° C. when histamine was added at a final concentration of $M/30$.

It may therefore be concluded that histamine inhibits neither cytochrome oxidase, succinic dehydrogenase, nor any enzyme active in the glucose phosphorylation cycle of anaerobic baker's yeast, and the biochemical mechanism of its specific action remains obscure.

## An Androstenetriol in Normal Human Urine

TEN years ago, while working at the University of Toronto, I isolated from human pregnancy urine a new solid alcohol which melted at about 263°. Afterwards, in collaboration with Dr. G. C. Butler, the same substance was isolated in an average yield of about 0·1 mgm. per litre from urine specimens from non-pregnant normal women and normal men, and the following derivatives prepared: an *acetate* (m.p. 189–191°), a *chloracetate* (m.p. 161–163°), a *hydrogenation product* (m.p. 257·5–259°), an *acetate* and a *chloracetate* of the latter (m.p. 174–176° and 180–182° respectively), and a lead *tetra-acetate oxidation product* (m.p. 199–201°). At the time, analyses of these derivatives could not be reconciled with any of the formulæ which the analysis of the parent substance seemed to indicate, and consequently the findings were not published.

More recently, Hirschmann[1] has isolated from the urine of a boy with an adenocarcinoma of the adrenal cortex large amounts of a steroid (m.p. 265–270°) identified as a $\Delta^5$-androstene-3(β),16,17-triol. For the following reasons it is believed that this substance is identical with the one isolated by Dr. Butler and me from normal human urine:

(1) The analyses of the above-mentioned derivatives (but not of the parent substances) are in close agreement with those required by theory; (2) the melting points of the androstenetriol triacetate (187–188·5°), the androstanetriol (256–260°), and the androstanetriol triacetate (175·5–176·5°) as reported by Hirschmann agree closely with those of the corresponding derivatives of the compound from normal urine; and (3) the melting points of the acetate and of the acetate of the hydrogenation product were not depressed by admixture with androstenetriol triacetate and androstanetriol triacetate, specimens of which were very kindly supplied by Dr. Hirschmann.

The original difficulty in reconciling the analyses of the derivatives with those of the parent compound can probably be ascribed to the presence in the latter of solvent of crystallization, since certain of Hirschmann's preparations of the androstenetriol gave analytical figures indicating the presence of half a molecule of methanol of crystallization.

Hirschmann has raised the interesting possibility that this androstenetriol may be produced from dehydro*iso*androsterone by a metabolic process similar to that involved in the conversion of œstrone to œstriol. The finding of this androstenetriol in normal human urine is of considerable interest, since it shows that the metabolic process by which it is formed is a normal one.

## Identification of Trypanosomes by Chromosomes

FOLLOWING a suggestion by Dr. H. Fairbairn, sleeping sickness officer, Tanganyika Territory, namely, that it might be possible to distinguish *Trypanosoma brucei, gambiense* and *rhodesiense* by the appearance, or the number, of chromosomes in each, the majority of the recognized chromosome-staining techniques were explored. Two methods gave good results, either using dried blood films from rats with very heavy infections, or probes of infective tsetses. The latter is a new method devised by Dr. E. Burtt, entomologist, at the Trypanosomiasis Research Station, Tinde, Tanganyika, in which the fly is caused to salivate upon a glass slide; I have modified the original method, in order to facilitate the handling of large numbers of tsetses. (*a*) The films are fixed with acetic alcohol[1] and stained with Giemsa or hæmatoxylin. (*b*) The films are hydrolysed for 4–6 minutes in normal hydrochloric acid at 60° C. and then stained with Giemsa for 1–2 hours.

It has only been possible so far to examine *Trypanosoma rhodesiense* (Tinde strain) and *T. congolense* (Shinyanga strain). Mitosis occurs in both these species, as has been previously noted by several authors, quoted by Wenyon[2]. The present observations show that *T. rhodesiense* has two types of individuals, one homoploid, with two paired and two unpaired chromosomes ($N = 6$) and the other heteroploid with two paired and one unpaired chromosomes ($N = 5$). *T. congolense* has also been observed to have two types of individuals, one with three paired chromosomes and the other with three paired and one unpaired chromosomes.

It appears, although this is not yet confirmed, that meiosis may also take place, the unpaired chromosomes acting like the sex chromosomes of other animals, and that gametes are thrown out by the meiotic trypanosome. The latter are presumed to unite with the reduced nucleus of another trypanosome, but this has not yet been observed. Fry[3] observed and recorded objects he considered were gametes being extruded from a trypanosome. I have observed similar flagellated objects near the trypanosomes, and others that appear to be in the process of being extruded, in a stained (acetic-alcohol–Giemsa) slide of *T. congolense* from a probe of a laboratory-infected *G. morsitans*.

Work on these lines is being continued, and it is hoped to publish a fuller account elsewhere later.

## Electro-magnetic Wave Crystals

AT the conclusion of her very interesting lecture on "Diamonds, Natural and Artificial"[1], recently given at the Royal Institution, Dr. Kathleen Lonsdale mentioned past attempts at producing artificial diamonds by dissolving graphite in a molten metal at a very high temperature and letting the solution solidify under very high pressure. There is, in her judgment, strong evidence that some of the recorded attempts were successful.

I would suggest the possibility of another method of producing artificial diamonds which appears to me worth investigating, particularly in view of the much wider field which it may open.

The essence of this method consists in causing crystallization to proceed in a space filled with stationary electro-magnetic waves with the nodal points corresponding to the positions of the atoms in the crystal. It seems that in this way any feasible atom lattice can be realized, for it can be shown, on the lines which I used for determining stable positions of a rotating electron beam[2], that these nodal points will also be the points of maximum stability of corpuscles. Such an electro-magnetic wave pattern can be called an 'electro-magnetic wave crystal'.

The simplest electro-magnetic wave crystal corresponding to the diamond will be formed by three intersecting sets of plane stationary waves with the nodal planes determined by the sets of directional cosines 100, $\frac{\sqrt{3}}{3}\ \frac{\sqrt{3}}{3}\ \frac{\sqrt{3}}{3}$, and $\frac{\sqrt{3}}{3}\ \frac{\sqrt{3}}{3}\ -\frac{\sqrt{3}}{3}$, and the wave-lengths of travelling waves, propagating in opposite senses and thus forming stationary waves, 1·78 A., 2·06 A. and 2·06 A. respectively. It seems that a diamond could be obtained by solidification of carbon vapour in such an electro-magnetic wave crystal. It may be that this was actually the way in which the natural diamonds were formed, and that their rarity is due to the small probability of spontaneous formation of the corresponding electro-magnetic wave crystals.

It should be possible to extend this method to controlling the formation of any chemical compound by causing an appropriate chemical reaction to take place in an electro-magnetic wave crystal corresponding to the lattice structure formed by the atoms of the compound. For this purpose it would probably not be necessary to form a complete electro-magnetic wave crystal, in which every single atom of the compound should find its corresponding place; it might be sufficient if the crystal were to accommodate the unstable atoms of the molecule and a sufficient number of atoms of the stable part of the molecule to determine the position of the molecule. There are various possible biochemical and even therapeutic implications of this train of ideas.

The stationary electro-magnetic waves forming such crystals can be produced by interference of monochromatic beams of X-rays or by using electron diffraction. The technical difficulties involved in the construction of an apparatus for this purpose do not appear to be unsurmountable.

It is doubtful, however, whether the work of a single investigator could yield sufficient results, within a reasonable time, to provide the requisite stimulus for further progress along these general lines. I do not expect to be able to undertake anything of the kind myself in the near future, and publish the suggestion in the hope that some who have the opportunities and equipment may be inclined to follow it up.

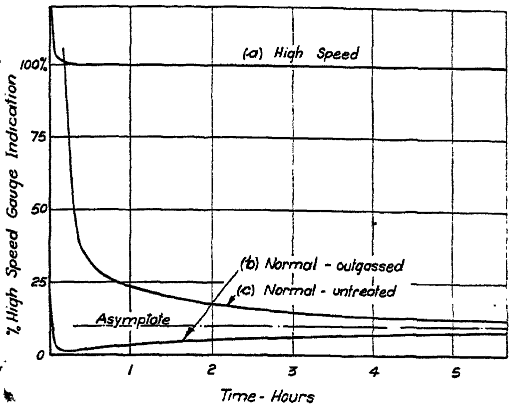
## Use of the Ionization Gauge on Systems Evacuated by Oil Diffusion Pumps

THE ionization gauge is in almost universal use for the measurement of extremely low pressures, and whereas much careful work, for example, Dushman's classical experiments[1], has established its accuracy for permanent gases, very little work which throws any light on the possible sources of error when the gauge is used on systems evacuated by organic vapour pumps has been published.

Some experiments recently carried out in this laboratory have shown that, unless certain precautions are taken, the observed ionization current may be as small as one hundredth of that corresponding to the vapour pressure of the pump fluid. This result was discovered during experiments to determine the errors which would occur if a specially designed ionization gauge were used without degassing, the following procedure being adopted.

Two gauges having identical electrode structures, but with tubulation speeds of 0·7 litres/sec. and 80 litres/sec. respectively, were connected to the same vessel. The vessel, which had a volume of 10 litres and an internal surface area of 5 sq. ft., was evacuated by a standard commercial oil diffusion pump of speed 23 litres/sec. After running this pump for several hours, during which the first (or normal) gauge was ovened and bombarded to remove occluded gases, no treatment whatever being applied to the second (or high-speed) gauge, the two gauges were switched on simultaneously. Readings of the positive ion currents were then taken for a period of six to seven hours. The results of this test are shown by the curves *a* and *b* in the accompanying figure.

It will be seen that the pressure indicated by the high-speed gauge fell to a value within a few per cent of its final value within about five minutes. This is in marked contrast to the very considerable variations shown by the normal gauge, the indication of which first fell to a value just greater than 1 per cent of that for the high-speed gauge, finally increasing asymptotically to about 10 per cent of this value. It would appear logical to ascribe the high indication of the high-speed gauge to the fact that it had not been outgassed, but that this was not the case was



RELATIVE INDICATIONS OF NORMAL AND HIGH-SPEED IONIZATION GAUGES.

easily demonstrated, first by degassing it, when no appreciable change in its final indication was observed; secondly, by running the normal gauge without degassing, its final indication in this case approaching the same asymptote as in the first experiment, in the manner shown by curve c.

An alternative and more tenable explanation of the difference between the indications of the two gauges can be based on the statement of Gaede[2] that the ionization gauge itself acts as a pump and consumes the gas which diffuses into it. For this, among other reasons, Gaede dismissed the ionization gauge as being unsuitable for low-pressure measurements, but there appear to be few references to work where the possibility that gas consumption may vitiate the results has been considered.

Experiments so far carried out here indicate that the consumption of elementary gases and of some of the lighter organic gases such as methane and propane is negligibly small, but that the vapours of some diffusion pump fluids are consumed to a marked extent. Consumption appears to be due to two effects: (a) adsorption or condensation, which is very pronounced when the glasswork is newly outgassed, but which decreases as the concentration of condensate of the surface increases; (b) a consumption effect which does not change as time proceeds, and is probably caused by breakdown of the heavy oil molecules by the hot filament. The former effect, which has also been observed by Hickman[3], accounts for the very low pressure shown early in curve b and for the gradual increase of pressure up to the asymptote. The latter phenomenon was observed by M. R. Andrews[4] in her studies on the reaction between tungsten and naphthalene; but its effect on the accuracy of the ionization gauge has not previously been considered. It accounts for the fact that the asymptotic value of the ionization current for the normal gauge is only 10 per cent of that of the high-speed gauge, irrespective of the time the gauges have been running.

The main conclusion of this communication is that in cases where the vapour of the pump fluid forms a major constituent of the total pressure in a system, special care in the interpretation of ionization gauge measurements is required, and that wherever authors have been unaware of the fact of vapour consumption, the pressures they quote will be proportional not only to the vapour pressure and the ionization constant of the particular pump fluid, but also to the conductance of the tube connecting the gauge to the vacuum system. On the other hand, it will be apparent that by using a gauge which offers no resistance to the entry of gas or vapour from the system, the pressure drop in the connecting tube caused by gas consumption will be reduced to zero, and the third of these variables will thus be eliminated. At the same time, such a gauge (an approximation to which is given by the high-speed gauge used in these experiments) could be used without initial degassing and would be in equilibrium with its surroundings immediately on switching on.

## Doppler Effect in Positive Rays of Hydrogen

THE Balmer lines in the spectra of the positive rays of hydrogen show Doppler displacement $d\lambda$ given by the relation

$$\frac{d\lambda}{\lambda} = \frac{v}{c} \cos \theta,$$

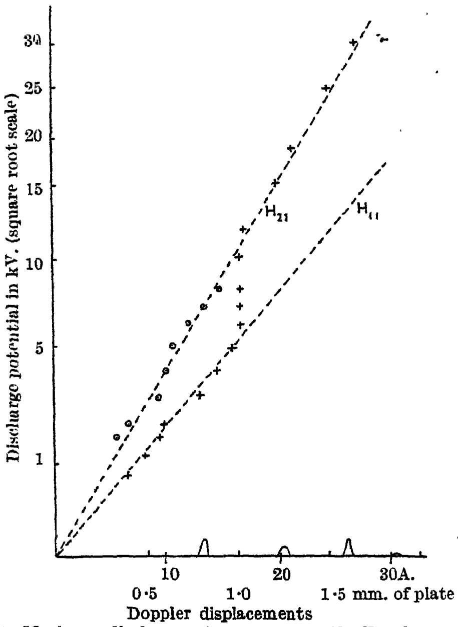
where $\lambda$ is the wave-length of the light emitted by a neutral atom of the positive ray beam, moving with a velocity $v$, the direction of motion of the atom making an angle $\theta$ with the direction of observation; $c$ is the velocity of light.

J. Stark[1], and J. Stark and Steubing[2] showed that whereas the Doppler displacement is not a line but a strip of finite width, the maximum displacement gave a value for $v$ which fell far short of the value to be expected from the relation

$$\tfrac{1}{2} mv^2 = eV,$$

where $e$, $m$ and $v$ are the charge, mass and velocity of the atom respectively, and $V$ is the difference of potential across the electrodes in the discharge tube in which the positive rays were produced. Paschen[3] found that for $V$ varying from 525 volts up to 24,000 volts the maximum Doppler displacement did not show any appreciable increment at higher voltages with increase of voltage. The maximum obtained corresponded to a voltage equal to 5,000. H. Krefft[4] and K. Lion[5] found that the maximum displacement did not remain constant but increased continuously up to 70 kV. and 130 kV. respectively. The values fell short of what is to be expected theoretically. Ney-Valerius[6], who worked at voltages of about 1,000, found values agreeing with the theoretical values.

We have made a systematic investigation, taking special care to see that the maximum values of the Doppler displacement as measured are really the maximum obtainable, and that they are not falsified or minimized for want of adequate exposures on the photographic plates. This has been made possible by taking spectra with varying times of exposures. The maximum so obtained for any one voltage was



+, Maximum displacements measured on the $H_\beta$ plate; ⊙, less displaced maxima; background lines are marked by curves on the abscissa.

found to be constant within wide ranges of the times of exposure.

In the accompanying graph the maximum Doppler displacement actually measured for $H_\beta$ has been plotted against $\sqrt{V}$. Theoretically, all the points should fall on the dotted straight line $H_{11}$. Actually, however, it is seen that the points lie on this line only up to a voltage of 5,500. Between 5,500 and 11,000 volts there is no change in the displacements. The points lie on the straight line $H_{21}$ from 11,000 up to the highest voltage used, namely, 30,000. This line, $H_{21}$, has been drawn theoretically like the line $H_{11}$ with $m$ replaced by $2m$. It follows, therefore, that above 11,000 volts the atom responsible for the maximum Doppler displacement has been derived by dissociation of a molecule of hydrogen accelerated in the discharge tube as a singly charged ion; the dissociation is supposed to take place after leaving the field. Ionized molecules are known to be present from the electromagnetic analysis. The potential 5,500, which corresponds to the value of the maximum Doppler displacement measured in the region of transition from the $H_{11}$ line to the $H_{21}$ line may be regarded as a transition potential.

A relation similar to that with $H_\beta$ has been found by us to hold good for $H_\gamma$ also, between the same limits of voltages. The transition potential for this line, however, is lower, namely, 3,500 volts. The value of the transition potential for $H_\alpha$ may be expected to be higher than that for $H_\beta$. It may, by extrapolation, be taken as about 7,000 volts. On the basis of the theory of ionization by atomic impacts developed by G. Joos and H. Kulenkampff[7], the value of the ionization potential is 6,200 volts. It appears, therefore, as likely that the ionization potential determines the transition potential.

An account of the experimental details and further discussion will be submitted for publication elsewhere; see also the doctorate dissertation, Benares Hindu University, 1938, by one of us (G. K. Das), and the note, by one of us (B. D.) and C. Dakshinamurti, below.

## Ionization Potential and Doppler Effect in Hydrogen Positive Rays

IN the note above by G. K. Das and one of us (B. D.), it has been pointed out that the transition potential as defined therein with positive rays of hydrogen for the $H_\alpha$ line should be about 7,000 volts. We have carried out a systematic investigation with this line, the current being kept constant at all potentials with times of exposure varied within wide limits. The results are shown in Fig. 1.

It may be seen that the transition potential comes

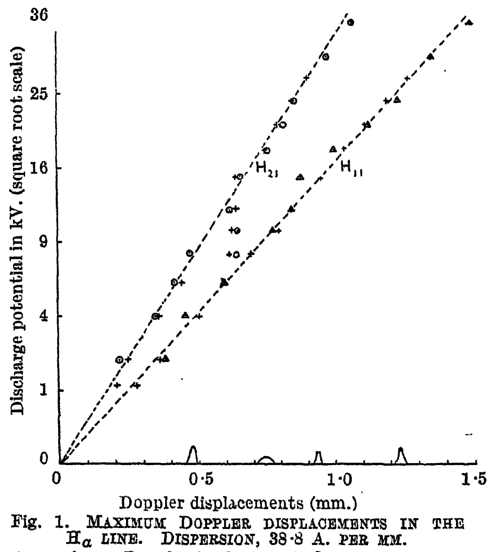

Fig. 1. MAXIMUM DOPPLER DISPLACEMENTS IN THE $H_\alpha$ LINE. DISPERSION, 38·8 A. PER MM.
△, maximum Doppler displacements }graded exposures.
⊙, less displaced maxima
+, exposures of 2 hr. each on a single plate.

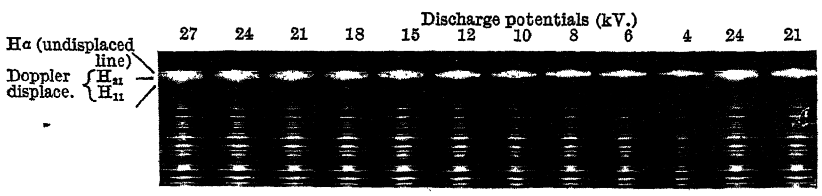

Fig. 2. VARIATION OF DOPPLER DISPLACEMENTS WITH VOLTAGE. NOTE THE INCREASING INTENSITY OF THE $H_{11}$ STRIP AT HIGHER VOLTAGES; TIMES OF EXPOSURE ARE CONSTANT, 2 HR.

out as 7,500 volts. This voltage is in fair agreement with the theoretical value of ionization potential of 6,200 volts on the basis of the theory of ionization with atomic collisions as developed by Joos and Kulenkampff[1], and it is in very good agreement with the values of the ionization potential as directly measured by Bartels[2], namely, 7,000 volts.

The most interesting result in this investigation is the presence of a strip which gives points for the full maximum Doppler displacement falling on the $H_{11}$ line for all the potentials studied, namely, up to 35,000 volts. This strip is faint in the transition region, namely, between 7,500 and 15,000 volts, but becomes increasingly prominent with rise of potential used; see Fig. 2, which is reproduced from a plate on which exposures with different potentials have been taken on the same plate and the time of exposure under each potential used was two hours, in order to be able to estimate the relative intensities independent of time and development. To check that the conditions of experiment have not altered, the first two exposures on the plate were repeated at the end.

Previous investigators were not able to establish agreement between the experimental and theoretical maximum Doppler displacements for potentials above 5,500 volts.

We have carefully investigated the maximum Doppler displacements for the $H_\beta$, $H_\gamma$, $H_\delta$ and $H_\varepsilon$ lines also, in order to be able to understand the outstanding behaviour of $H_\alpha$. A discussion of the same, particularly with reference to measurements carried out by Anna I. Mcpherson with homogeneous beams of positive rays which were made for $H_\beta$ and $H_\gamma$ only, will be reserved for consideration elsewhere; see also doctorate dissertation by one of us (C. D), Benares Hindu University.

## Roozeboom's Solid Solution Diagram, Type II

Prof. A. N. Campbell, of the University of Manitoba, has suggested[1] that this type of diagram should no longer be mentioned in treatises dealing with the phase rule. A similar opinion is also held by Prof. Jaenecke. I find this conclusion inadmissible for the following reasons.

(1) Roozeboom, in his classical study on the equilibrium of solidification with formation of mixed crystals, asserts this from a purely thermodynamic point of view without reference to the stoichiometric interpretation of the phenomena; consequently, so long as a single example of such a type of equilibrium is known, it is not legitimate to omit a description of it when enumerating possible cases.

(2) Prof. Campbell seems to believe that examples of this type are known only in the case of two pairs of optical antipodes. This is an obvious error. The following examples may be cited: (*a*) Other mixtures of enantiomorphs of which the melting-point curve shows a maximum: secondary butyl hydrogen phthalate[2]; $\alpha$ bromocamphor[3]. (*b*) Other mixtures: 1.2.4.6.tribromtoluene plus 1.2.3.5.tribromtoluene[4]; phenol plus cyclohexanol[5]; bismuth plus thallium[6]; lead plus thallium[7]. None of the maxima in (*b*) corresponds to a simple stoichiometric relationship. (*c*) Finally, if one takes into account the analogous equilibrium between mixed crystals and solvents, Clendinnen and Rivett[8] have described a series of mixed crystals formed by $2NH_4Cl.MnCl_2.2H_2O$ with $MnCl_2.H_2O$ on one hand and $NH_4Cl$ on the other, passing through a minimum of isothermal solubility corresponding to a maximum melting point.

The number of these examples alone shows the necessity of retaining Bakhuis Roozeboom's exposition in its entirety.

(3) Van Laar's demonstration, which Profs. Campbell and Jaenecke mention, does not appear to me to be so very convincing, because van Laar's calculations are based on the introduction of van der Waals' equation (contrary to what Prof. Campbell affirms); in fact, the values of $\alpha$ are calculated with the aid of the terms $a$ and $b$ of the van der Waals' equation as van Laar states expressly on p. 218 of his text.

(4) In order to decide which stoichiometric interpretation to give to such a maximum in the solidification curves, Prof. Jaenecke's considerations do not strike me either as being convincing, though I consider his conclusion as probable. As shown above, the maximum does not always correspond to simple stoichiometric proportions; this fact is almost fatal, as is proved by the outline of the solidification curves themselves, of which the maximum is flattened; consequently, the addition compound existing in the solid phase partially dissociates on melting; and it is quite possible that the addition of one of the products of dissociation to the compound will raise its melting point and thus displace laterally the maximum.

In order to decide in such a case whether one is dealing with a definite compound or a simple hylotropic solution[9], the safest way would be to study the equilibrium of melting under various pressures; if it is a hylotropic solution, the concentration at the observed point will vary continually with pressure, whereas it will remain fixed in the case of a definite compound; this experiment is analogous to the one by which Roscoe and Dittmar proved that the azeotropic mixture $H_2O+HNO_3$ is not a definite compound. But in the present case, in consequence of the slight influence of pressure on the melting point, it is essential to work under pressures varying between limits of several hundred or thousand atmospheres, using, for example, the method of 'piezometric' analysis as perfected by my collaborator L. Deffet and myself[10]. This experiment has not yet been made, but Clendinnen has carried out a similar one by studying the variations of the positions of the minimum of the curve of isothermal solubility at different temperatures, and has proved that in his case it was a hylotropic solution and not a compound.

(5) But in the case of a mixture of optical antipodes such as that discussed by Campbell and Jaenecke, this test fails because the diagram is perfectly symmetrical, from 50 to 0 per cent and from 50 to 100 per cent, owing to the identity of the thermodynamic properties of the two antipodes. It is therefore impossible, strictly speaking, to prove precisely in this particular instance whether the maximum melting point arises from the existence of a definite compound or whether it is a simple hylo-

tropic solution in a diagram perfectly symmetrical at all pressures. But I agree from other considerations that the maximum corresponds there to a definite compound.

*Conclusions:* In a communication which I recently made to the Second Education Conference held by the Association of University Professors and Lecturers of the Allied Countries in Great Britain on April 15, I complained of the fact that in the Anglo-Saxon countries too little use was made of original publications by scientific men on the Continent, with the exception of those from Germany, which appear to be widely read. I should like to emphasize that the foregoing discussion is an excellent case in point.

In my treatise "Les Solutions Concentrées", published in Paris in 1936, in which I gathered together all the known examples of mixtures of two organic components, will be found most of the systems mentioned above. The arguments developed in paragraphs 4 and 5 on the interpretation of the maximum melting point of mixtures of optical antipodes may be found at length in Chapter 4 of another work of mine published in Paris in 1927 and of which an English translation was made by my colleague, Prof. R. E. Oesper of Cincinnati University. This appeared in London and New York in 1940 under the title of "Chemical Species" (see Chapter 4, pp. 18–24).

## 'Soil' Mechanics

THE objections raised[1] to the name 'soil mechanics' are timely and cogent, but the difficulty is too deep-rooted to be disposed of by a mere change of the title of the science. The main trouble would appear to be the continued use by engineers of the term 'soil' for material which is not soil in the generally accepted sense, but comprises all soft and loose deposits, namely, gravels, sands, silts, clays and peats. Some workers in soil mechanics also adopt with altered significance other expressions (for example, soil profile) which were first used and are now well established in pedology (soil science).

With the two sciences of soil mechanics and pedology both in a stage of early and rapid development, it is a matter of urgent necessity that steps should be taken to prevent the clashing of terms.

Soil mechanics was christened at the International Congress of Soil Mechanics and Foundation Engineering at Havard in 1936, and appears to have received considerable impetus in Britain after the James Forrest Lecture at the Institution of Civil Engineers by Terzaghi in 1939. Examples could be given from several soil mechanics text-books in which the difficulties of trying to retain a dual usage of the word 'soil' are apparent. In fact, acquaintance with the literature leaves one in no doubt that the adoption of 'soil' to refer to unconsolidated deposits in general has resulted in considerable ambiguity and confusion.

The word 'earth' was in common use in early engineering literature in Great Britain and it is used by some writers on soil mechanics to explain what they mean by 'soil'. It would appear, therefore, to be a more appropriate term and, although not without some objections, it is well established in engineering parlance (for example, earthwork, earth dam, earth pressure). There seem to be few objections to 'earth mechanics' or 'earth statics', provided 'earth' is defined as meaning unconsolidated deposits and excavated material. It is questionable whether engineers would readily accept 'geostatics', and, to the geologist, the prefix suggests something more profound than the surface layers encountered in engineering structures. However, as already stated, the name of the science is not the major issue, which is the misuse of the word 'soil'.

## The Concept of Force

A FINGER pressed against a table has sensations of contact and muscular sensations of resistance. Prof. H. H. Price, in his presidential address to the Aristotelian Society on February 11, analytically supposes the finger to have the muscular sensations only. The owner would have a notion of *force* through these muscular sensations, but no notion of matter because he has no sensations of contact. Thus a being who experiences muscular sensations and never experiences sensations of contact would be "aware of pure force, disembodied force as it were".

When a motor-car turns sharply round a corner the passenger feels as if he were shoved, but not as if a thing shoved him. This centrifugal experience, Price notes, gives the normal human being an experience of "pure force". Also, the supposititious being who has this experience only, because no contact sensations assure him of material things, would fully appreciate the "fields of force" of physics.

The contents of sensory experience are presumably embodied in concepts of *force*, and, however unreflective the embodiment may be, analysis can legitimately expect to disclose it. The talks in the "Hermetica", which were probably finally collected in the third century A.D., are pervaded by a sense of pervasive forces. The talks collect ideas rather than systematize them, and the items in this Greco-Egypto concept of force can be again collected from them into a précis. The forces are efficacious, immortal, imperceptible, unextended, radiative and, though incorporeal, only work in bodies. This concept of force is well compounded; the "radiative", for example, has probably an analogue in solar rays, but the *incorporeal* corresponds to the revelation of "disembodied force" by muscular sensations, and the "only work in bodies" corresponds to the normal connexion between force and material bodies through sensations of contact.

# RESEARCH ITEMS

### Causes of Death in Fishes in Captivity

A REPORT on the causes of mortality of fishes exhibited in the New York Aquarium at Battery Park, New York City (now closed), is given by Ross F. Nigrelli (*Zoologica*. Scientific Contributions of the New York Zoological Society, 28, Part 4, No. 22; 1943). Careful attention and research have reduced the mortality very considerably in the last few years and all diseases and epidemics are well under control. There are many factors, however, which may cause death besides parasites and disease. Overcrowding is important, sudden change in temperature, the wrong adjustment of light, range and degree of $p$H, density, amount of oxygen, chlorine and nitrogen in the water, metabolic waste products and diet—all cause mortality; also too much handling and too frequent removal from one tank to another. It is established that the fishes themselves contribute largely to their own well-being in fitting themselves to their environment. There is a definite population density of fishes for a given volume of water and the fishes will kill one another off to maintain equilibrium when all other ecological factors are equal. They can, and do, control to a certain degree the chemical contents of their environment. This paper is full of valuable information and should be studied by all who are interested in aquaria.

### Chondrocranium and Visceral Arches of Ascaphus

H. K. PUSEY (*Quart. J. Micro. Sci.*, 84; 1943) has provided an account of the chondrocranium and visceral arches of the frog *Ascaphus truei*, illustrated by seven text-figures and nine plates and containing a comparison with the conditions obtaining in the Urodela and other Anura. G. K. Noble, in a recent classification of the Anura, places Ascaphus with a New Zealand genus Liopelina in a separate family and regards it as the most primitive family of the Anura. The author of the present paper, as the result of his detailed studies, agrees with this, and hence a knowledge of the chondrocranium in this family is essential for an appreciation of the relationships of the higher Anura and of these to the other Amphibia. Ascaphus has more characters in common with the Urodela than the larva of any frog hitherto described, and is in some respects even more primitive than any living Urodele or indeed other living Tetrapod. The most nearly related family of the Anura appears to be the Discoglossidæ. It is not possible within the limits imposed to enumerate all the points brought out, but the consideration of the cartilages and muscles in this form do permit of criticisms of previously proposed interpretations regarding them in Anura and also Stegocephalia. As is only to be expected, Ascaphus possesses certain individual specializations which are clearly indicated.

### Taxonomy of Onchidiidæ

THE family Onchidiidæ has frequently been placed in the Pulmonata, although it has been generally recognized that it has affinities with the Nudibranchs. It has also been regarded as belonging to the Opisthobranchs by other authorities. The recent work of Vera Fretter on *Onchidella celtica* (*J. Mar. Biol. Assoc.*; 1943) has finally provided a solution to this problem and shown that the family is to be regarded as an early offshoot of the Opisthobranchs. In structure the veliger of Onchidella resembles that of the monotocardian prosobranchs, but it lacks a ctenidium and an osphradium. It has a cavity on the right side and, although at this early stage there is no genital aperture, this is to be regarded as a true mantle cavity. During metamorphosis detorsion takes place, and this cavity moves round to the posterior end, carrying with it the anus and kidney opening. At the same time the cavity closes up to become a narrow tubular space and its aperture contracts to a pore. The result of this is that a bilateral symmetry is once again established and the pore at the hinder end of the mollusc, until now regarded as the anus, is, in fact, the opening into the reduced mantle cavity. The metamorphosis is accompanied by a reduction of the visceral hump and the loss of the shell.

### Genes and Cytoplasm

SEVERAL papers recently have reported unsuspected relations between genes and cytoplasm in the production of a phenotypic character. T. M. Sonneborn (*Proc. U.S. Nat. Acad. Sci.*, 29, 329; 1943) describes a remarkable case in *Paramecium aurelia* where a pair of characters, 'killer' and 'sensitive', exhibit this phenomenon. *P. aurelia* individuals carrying 'sensitive' are killed by fluid in which 'killer' individuals have lived. An $F_1$ between killer and sensitive shows that vegetative 'killers' all derive their cytoplasm from 'killer' and 'sensitive' cytoplasm from 'sensitive' parents. Further, a gene $K$ in cytoplasm of race 51 gives 'killer' but not in cytoplasm of race 32. However, if the sensitive gene $k$ is carried in race 51, this race does not develop killer when $K$ is again introduced. Experiments show that the cytoplasm develops a definite substance in the uninterrupted presence of $K$, but $K$ alone cannot produce this killer reaction. Thus 'killer' depends on a gene $K$ and a cytoplasmic substance. This substance is kept in production by $K$, but $K$ alone cannot initiate its production. Sonneborn points out the resemblance of this peculiar behaviour with that in other organisms. For example, cytoplasmic inheritance in plants is closely parallel to results in *P. aurelia*. In this species, however, race 32 contains $k$, which is allelomorphic to $K$. In its presence the cytoplasm ceases to exert its previous influence on the killer character. The antigenic complex of Pneumonococcus may also be compared with *P. aurelia*. Here antigenic types may be transformed into one another by suitable alterations in the environment. It is suggested that a gene of Pneumonococcus will induce the cytoplasm to continue the production of an antigene when the basic substance is already present, but that it cannot initiate this substance. Adaptations may also be of this type, sometimes as in the acquired ability of *Propionibacterium pentasaccarrum* to synthesize vitamin $B_1$ after being supplied with this substance. Mutations may not only be genic or chromosomal in type, but also sometimes may be of this cytoplasmic reaction form.

### Fungus Diseases of Fruit Trees

THREE recent short papers (*J. Pom. and Hort. Sci.*, 20, Nos. 3 and 4; Oct. 1943) describe new diseases of tree fruits. Dr. H. Wormald has isolated the fungus *Cylindrocladium scoparium* from shoots of plum and cherry varieties raised for rootstocks, and has proved its pathogenicity. Fructifications are rarely found on wilted shoots, though microsclerotia are common. Control methods which are suggested

include the dipping of infected stool shoots in Bordeaux mixture. The same author also describes the appearance of papery-bark canker on trees recently top-grafted. The fungus *Stereum purpureum* was isolated from several grafts, but one of them yielded *Polystictus versicolor*. A disease of apple fruits, known as dry eye rot, has been investigated by E. H. Wilkinson. *Botrytis cinerea* is the causal fungus; it attacks through an injured calyx, forms an initial eye rot, remains quiescent for a period, and later involves a complete rot of the whole fruit. Change from a high humidity to drier conditions prevents the progress of the disease to a complete rot.

### Diamonds in the Bolivian Andes

A RECENT discovery of diamonds in the river gravels of the Caupolican district of north-east Bolivia is reported by V. Oppenheim (*Econ. Geol.*, **38**; 1943). The diamonds are associated with gravels derived from Permian tillites. The latter are made up of rocks which are not found in the region but have evidently been transported by Permian ice from the basement metamorphic and igneous rocks of the Brazilian Shield, far to the east. In 1936 the author described the diamond-bearing tillites of the Parana Basin in south-eastern Brazil and showed that the diamonds occurred in acid intrusive rocks such as are thought to be the source-rocks of the diamonds of eastern Brazil. It is suggested that the Bolivian diamonds have probably been derived from a similar source in the Shield, whence they have been transported by ice and concentrated by rivers. Closer investigation is proceeding with the view of ascertaining the possible economic importance of the placer deposits.

### Atmospheric Ozone Determination

E. Glückauf, H. G. Heal, G. R. Martin and F. A. Paneth have described (*J. Chem. Soc.*, 1; 1944) a semi-portable apparatus for the continuous recording of the local concentration of atmospheric ozone. Iodine is liberated by the ozone from sprayed buffered potassium iodide solution and is electrometrically titrated at short intervals with very dilute sodium thiosulphate solution. The small current resulting from the depolarization of a pair of platinum electrodes by the iodine is amplified by a two-stage valve amplifier, and made to actuate an automatic burette containing the thiosulphate solution when the iodine concentration reaches a given value. The whole apparatus is actuated by the A.C. mains.

### Ascorbic Acid as a Photographic Developer

ASCORBIC and *iso*-ascorbic acids have been known as photographic developers since 1934, and formulæ for such developers have been published. Their oxidation products do not interfere with the development process. In presence of a suitable amount of bromide, the two acids yield good image development with only slight fog formation; they show no unusual properties and in general resemble hydroquinone, apart from the lack of activity of the oxidation products. T. H. James (*J. Amer. Chem. Soc.*, **66**, 91; 1944), who has established these results, also finds that the *iso*-acid reacts at a somewhat greater rate. At $pH = 10$ the active developer consists almost entirely of the bivalent ion, which is adsorbed prior to reaction with the silver bromide. In caustic alkali solution, diffusion rates determine the measured development rate. The rate increases with nature and concentration of salts present, the effect being caused by a depression of the double-layer zeta-potential of the silver bromide; this permits greater penetration of bivalent ascorbic acid ions through the double-layer region to the surface of the grain.

### A New Electron-Optical Voltmeter

IN a paper read recently in London before the Institution of Electrical Engineers, Dr. L. Jacob described an electronic instrument for measuring A.C. or D.C. peak voltages in the range of 2–20 kV. to an accuracy of 3 per cent. The voltmeter has a low capacitance (9 cm.) and can be used in some circuits up to frequencies of 1 Mc./s. or more. Its action is based on the proportionality theorem for a triode electron-optical system, in that the angle of the beam is defined by the ratio of two voltages, the anode voltage and the voltage of the modulator grid. The beam angle remains constant when both terms of this ratio are multiplied by the same factor, the modulator bias voltage being directly proportional to the voltage to be measured when the latter is applied to the anode. A high voltage is thus measured in terms of a low voltage, the instrument constituting an electron-optical potentiometer. The range of measurement can be extended as desired. The same principle can also be applied to the construction of high-voltage tubes so that they act as their own voltage-measuring instruments.

### Quantum Mechanics of Fields

THE usual treatment of quantized field theories is not very satisfactory. According to a recent paper by Prof. M. Born and Dr. H. W. Peng (*Proc. Royal Soc. Edin.*, **62**, 40; 1944), the difficulties are somewhat similar to those which occurred in Bohr's semi-classical quantum mechanics of particles. These difficulties were overcome by replacing Fourier series by matrices. In the existing field theories we already have matrices, but we also have indices which do not belong to these matrices, and are related to Fourier series. In short, these theories are still partly classical. The remedy proposed by Born and Peng is to build up a new theory in which each field component is wholly represented by a matrix. The advantages of this are that the technique is much simpler and of the same type as that of ordinary quantum mechanics. The new theory can be applied to non-linear field equations without any mathematical complication, as the superposition principle holds for each state of a pure field. It is hoped to extend the work to account for the production of new particles from the primary ones.

### Trapezium Stars

Otto Struve and John Titus, of Yerkes Observatory, have studied the four stars forming the trapezium in the Orion nebula, and have found that the lines of these stars are displaced more towards the red than the emission lines of the nebula (*Sky and Telescope*, February). It is surprising to find these stars moving with twice the speed of recession of the Orion nebula, because they have usually been thought to be associated with the nebula. Dr. Struve suggests that the stars may shine brightly and yet be of small size but large masses, and that the Einstein effect is in evidence here, as with the companion of Sirius. If this is so, the excess of red shift may not be due to a higher speed of the stars than of the nebula.

# THE ASH TREE

By ALEXANDER L. HOWARD

THE ash stands alone among our forest trees in the peculiar shape and manner of its growth. Sculptors and artists have always been inspired by the grace and beauty of trees and all that the tree bears, so that we have exquisite models of the oak leaf, the acorn, the twisted and gnarled bark of many kinds of trees. The habit and growth of the limbs of the ash being distinctive, the artist has taken it as a model for the arms of the standard and other lights in cathedrals and churches, and the architect for the columns and fair tracery which support the vaulted roof similar to that of the forest glade.

Pliny says:

"There be many trees besides that Nature hath brought forth; for their wood of timber: and among them the Ash, which of all others, groweth most plentiously in every place . . . much ennobled by the praise and commendation that the Poet Homer giveth it, as also for the speare or launce of Achilles, made thereof. . . .

"The Greeks have made 2 kinds of the Ash: the one runneth up tall and even without a knot: the other is lower, more tough and hard, and withall, of a more brown and darkish colour. . . . Others have put a difference between Ashes, according to the places: for that of the plaine and champion country, hath a more curled and fristed graine than the other of the mountaines, but contrariwise, the wood of this is more compact and harder than the other. The leaves of this tree, according to the Greekes, are hurtfull, venomous, and deadly to horses, mules, and such labouring garrons; but otherwise to beasts that chew cud they be harmlesse. . . . Moreover, they be excellent good, and nothing so soveraigne can be found against the poison of serpents . . . nay, so forcible is their virtue, that a serpent dare not come neare the shadow of that tree. . . .

"A wonderful goodnesse of dame Nature that the Ash doth bloome and flourish alwaies before that serpents come abroad."

Yet it would be difficult to trace the original cause of the belief in the supposed efficacy of the cure by what was called the shrew-ash. Superstition has always held an overpowering influence over the mind of man. The medicinal qualities of trees and shrubs were far more generally known and practised in earlier times, when qualified medical aid was difficult to procure, and the health of husband and children devolved far more on the housewife. It is probable that cures which had been effected by the use of the leaves, fruit or juices of the ash trees had actually been brought about, but certain it is that up to a hundred years ago, and even to-day, a belief still prevails in the curative powers of the shrew-ash.

The Rev. C. A. Johns says:

"They have also a superstitious custom of boring a hole in an Ash, and fastening in a shrew mouse; a few strokes with a branch of this tree, is then accounted a sovereign remedy against cramp and lameness in cattle, which are ignorantly supposed to proceed from this harmless animal."

Gilbert White (of Selborne) says:

"In a farm-yard, near the middle of this village, stands at this day a row of pollard-ashes, which, by the seams and long cicatrices down their sides, manifestly show that in former times they have been cleft asunder. These trees when young and flexible, were severed and held open by wedges, while diseased children, stripped naked, were pushed through the apertures, under a persuasion, that by such a process the poor babes would be cured of their infirmity. As soon as the operation was over, the tree in the suffering part was plastered with loam, and carefully swathed up. If the parts coalesced and soldered together, as usually fell out, where the feat was performed with any adroitness at all, the party was cured; but where the cleft continued to gape, the operation, it was supposed, would prove ineffectual. . . . We have several persons now living in the village, who in their childhood were supposed to be healed by this superstitious ceremony, derived down, perhaps, from our Saxon ancestors, who practised it before their conversion to Christianity."

Johns was of the opinion that John Evelyn half believed in the efficacy of this practice.

Many of our well-known arboriculturists have given us accounts of remarkable trees, among which Elwes mentions the Queen Ash at Ashridge Park. He says:

"One of the most perfect examples, from a timber point of view, is a tree growing in a wood called Poultridge, just outside Ashridge Park, which is about 125, perhaps 130 feet high. . . . It had, in 1906, an absolutely straight clean stem, about 75 feet in height by 11 feet 10 inches in girth, and looked as if it would square 27 to 28 inches halfway up, in which case it contains about 400 feet of faultless timber in one length."

The year in which the Conservative Party first occupied the house at Ashridge Park (about 1920) I visited the tree, to find that the measure had increased since Elwes's time. I was informed that an immense price had been offered for it and refused. Alas, within three weeks it was struck by lightning, which revealed that it was almost a hollow shell, with scarcely a sound piece of timber throughout the immense size. It was a strange case, as the tree displayed no sign, appearing perfectly healthy, sound, and clothed with a sound bark throughout. I have repeatedly seen oak trees struck by lightning, ash rarely, elm never; it would be interesting to discover the reason.

No tree repeats itself so vigorously as the ash tree, which through its winged seed spreads far and wide, producing innumerable young seedlings. No tree planted, or transplanted, will grow so sturdily and establish itself so surely. Every gardener finds self-sown ash trees springing up around his beds and paths in such profusion that they become a nuisance, and in those districts where ash plantations abound, every year a wide area of strong naturally regenerated plants will be found. A wiser control in the past would have protected these areas, so that at the least possible cost a wealth of young forest would have been added to our depleted woodlands. This course has never been pursued, and year by year young trees have been trodden down, ploughed up, or destroyed by animals.

While many of the trees grown in Great Britain have been wanted and from time to time have been realizable at varying prices—sometimes actually negligible—the demand for ash has remained constant, and the price regular. Even in Evelyn's time, nearly three hundred years ago, the great value of the ash was recognized. He says:

"In 40 years from the key (seed), an ash hath been sold for £300. sterling, and I have been credibly informed that one person hath planted so much of this one sort of timber in his life-time as hath been valued worth £50,000. to be brought." (£50,000 in his day would be equal to say £100,000 to-day.) "Every prudent Lord of a Manor should employ one acre of ground to Ash with every 20 acres of other land, since in as many years it would be more worth than the land itself."

There can be little doubt that the future will bring the fortunate owner a reward, as it is doing to-day, on a higher scale than any other tree which he could grow.

Of the innumerable species of ash trees which can be found distributed all round the globe, and in pro-

fusion in the United States, Canada, Europe, China and Japan, three kinds only will be referred to in this article—the common ash, the manna ash, and the weeping ash. The common ash (*Fraxinus excelsior*) was abundant in male and female trees before the War of 1914–18, before which time there had been a steady demand year by year; but there was no cause for alarm. With the wholly unexpected and prodigious requirements of the War, and the advent of the aeroplane, whole areas were entirely denuded of the finest trees. A search for straight, well-grown trees, suitable for aeroplane construction, was relentlessly pursued, and ash trees of sufficient length and of clean hard growth brought the owners prices the highest ever known. In the years following the War the demand continued with unabated vigour, and undesirable and unfortunate as it may be deemed, large consignments of trees were sold to Japan.

Through all ages the wood of ash has been used for a great number of purposes, and because of its character it has served a special purpose for which no other wood has been found equal. The early writers or historians continue to record its merits for service both in war and peace.

Johns says:

"As a timber tree the Ash is exceedingly valuable, not only on account of the quickness of its growth, but for the toughness and elasticity of its wood, in which latter quality it surpasses every European tree. In its younger stages (when it is called *ground-ash*), it is much used for walking sticks, hoops, and hop-poles; and it matures its wood at so early an age, that an Ash-pole, three inches in diameter, is as valuable and durable for any purpose to which it can be applied, as the timber of the largest tree. The use of Ash is (next to that of the Oak itself) one of the most universal: it serves the soldier (Spears were anciently made of Myrtle, Cornel and Hazel, but Pliny prefers the Ash for that purpose)—and heretofore the scholar, who made use of the inner bark to write on, before the invention of paper. The carpenter, wheelwright, and cart-wright find it excellent for plows, axle-trees, wheel-rings, and harrows; it makes good oars, blocks for pullies, and sheffs, as seamen name them: for drying herrings no wood is like it, and the bark is good for the tanning of nets; and, like the Elm (for the same property of not being apt to split or scale), is excellent for tenons and mortises; also for the cooper, turner and thatcher; nothing is like it for our garden palisade hedges, hop-yards, poles and spars, handles and stocks for tools, spade-trees, etc. In summer the husbandman cannot be without the Ash for his carts, ladders, and other tackling, from the pike, spear, and bow, to the plow; for of Ash were they formerly made, and therefore reckoned amongst those woods which, after long tension, has a natural spring, and recovers its position, so as in peace and war it is a wood in highest request."

The quality of the wood grown in Great Britain surpasses in its toughness and flexibility that of any other country, although some grown in Canada and some in the Transylvanian Alps approach it very closely. For the purpose for which it is used it would be difficult or even impossible to find a satisfactory substitute. With the advent of the aeroplane, ash became a far more important medium, one indeed on which the whole course of the War of 1914–18 was peculiarly dependent. Ash was used for the longerons, collapsible wheels, internal packing blocks, and for skids and runners for gliders, where length, straightness of grain, absence of imperfections, strength and toughness preserved the lives of flying men. Such was the demand that the whole available existing supply of seasoned wood was exhausted in a few months. Thousands of trees were cut down in Great Britain, and thousands were brought from the Continent. No less than twelve thousand trees could have been seen at one depot, in separate piles. The imported ash produced a longer length of clean straight growth than that grown in Great Britain, showing the advantage gained by scientific forestry practised abroad as compared with the absence of these methods in Great Britain. The largest drying kilns available were continually employed with day and night shifts, year in year out, without cessation, and wood from growing trees was actually in aeroplanes flying over the enemy's lines within a few months of the felling of the trees. Ash was also used for the keel pieces of the gondolas or boats of the blimps or airships. The length required for this purpose was exceptional, being about 26 ft. long, with a dimension of 1¾ in. by 4 in.—a demand which, although drastic, was fulfilled.

The ash tree is attacked by a fungus, the identification of which does not yet appear to have been determined. Everyone will have noticed spreading from the trunk, perhaps at the base, or at any other point to the crown, a collection of overhanging growths, in mushroom form. This is the outward manifestation of the fungus growth in the tree. Sometimes it forms in a part where vigorous young shoots are pushing out, which form what is known as a burr. With the ash tree, however, the fungus mingles with the wood growth, consolidating into one solid mass of apparently woody growth. Such burrs when cut through display the customary bird's-eye surface, but intermingled will be found thin black streaks circling in and out among the bird's-eye marking. Ash burrs, whether pure and white without fungus, or whether as described above, with fungus, have always been highly valued, and for three hundred years used by cabinet-makers in veneer fashion for the making of art furniture. Examples can be found, particularly in the cases of grandfather clocks, especially those made in the reign of Charles I. The fashion would seem to have insensibly fallen away, but has revived again lately.

We must not overlook the weeping ash (*Fraxinus excelsior* var. *pendula*), one of the most decorative forms that any tree bears. This tree appears to have been discovered about one hundred and fifty years ago, and Elwes says:

"Loudon describes several forms of it, and says that the original tree was discovered near Wimpole in Cambridgeshire 150 years or more ago,"

and he refers to another form, "the Cowpen Ash", which he says has "assumed a very similar habit"; and still another, the Kincairney Ash, which "was distinguished by its alternately pendulous and upright branches". He reports a weeping ash, by far the finest known, which was grafted about 1848 at Elvaston Castle, near Derby, and was reported as being 98 ft. high, with long weeping branches, and another with a bole 50 ft. by 12½ ft.

Apparently it is necessary to rear this tree only by means of grafting on to the ordinary common stock, a proceeding which has much been neglected, but which if pursued would give additional interest and much pleasure to those who are concerned with arboriculture. No doubt the enterprising nurseryman will have continued to produce the weeping ash for his customers, but its popularity to-day is insignificant in comparison with about one hundred and forty years ago. The beautiful examples then established can be seen in almost every park and garden, in the gardens of country houses, in the public parks, in cities and the surrounding gardens, and in the botanical gardens,

but the youthful tree which should take its place is conspicuous by its absence to-day.

The manna ash (*Fraxinus ornus*) is another beautiful tree, far too little known or appreciated in Great Britain. It is said to have been introduced by Dr. Uvedale in 1710 from southern Europe. Elwes says the tree was common "in Eastern Spain, Corsica, Sardinia, Italy, Servia, Bosnia, Greece, and Asia Minor".

Later he adds:

"Its chief economic importance is due to its being the source of manna. The manna of commerce, according to Hanbury, is exclusively collected in Sicily . . . incisions are made in the bark . . . and the manna exudes as a clear liquid, which solidifies on the stem of the tree or on pieces of straw or wood that are inserted in the incisions. Manna consists mainly of a peculiar sugar called mannite, which is a mild laxative and is employed as an officinal drug in many countries."

So far as it is possible to ascertain, no use has been made of the manna ash tree for the production of manna in Great Britain, as has been the case in Sicily and southern Europe.

So little is this tree known that the owner of a house had one of them on her lawn, which she highly prized, and which for years was appreciated by those who visited her, but every inquiry she made failed to reveal its identity.

The tree thrives well, and under good conditions will reach a height of 50–60 ft., with a maximum recorded girth of 8 ft. 8 in. A very fine specimen can be seen at Kew, the measurement of which is given by Elwes as 60 ft. high by 7 ft. 6 in. girth. A very fine grove of these trees can be seen near the Castle at Arundel.

A young tree, but already with a beautiful habit, can be seen near the Epstein statue in Hyde Park. This tree, about seven years ago, was heavily loaded with seed, of which I obtained a quantity, and from which I reared three hundred and fifty trees, some of which are now 8 and 9 ft. high. Whether these trees will revert to the original stock or prove to be true manna ash (*F. ornus*) remains to be seen. Generally, if not always, it has been grafted on to a stock of the common ash (*F. excelsior*).

The trunk, with a smooth grey stem, supports the crown, whence branches somewhat drooping bear a rich foliage, not unlike the common ash, but with a more rounded and delicate leaf. Dr. R. Melville says:

"The Manna Ash, . . . exhibits a fair degree of variation in leaf form. There are at least two varieties described of the Manna Ash based upon leaf shape."

The lovely whitish flowers give off a delightful perfume, which permeates the air around the tree.

The wood is of finer grain, but otherwise similar to that of the common ash, but so rarely provided that it is generally unknown to the craftsman.

# CHOLESTEROL METABOLISM IN THE ANIMAL BODY

By Dr. G. A. D. HASLEWOOD

Guy's Hospital Medical School, University of London

THERE has been a considerable amount of recent work on the unsaponifiable fatty material of several types of animal tissue, and one of the results of this kind of experiment has been to throw some light on the changes which probably take place during life in the substance cholesterol (I), a ubiquitous constituent of animal cells.

By no means the least interesting aspect of this research is the somewhat unexpected discovery that the changes undergone by cholesterol are so easily brought about that it is often impossible to say with certainty that they might not have occurred during the processes leading to the isolation of the resulting products from the tissue extract. Moreover, Bergström and Wintersteiner[1] have shown that purified cholesterol itself can be transformed under conditions of *p*H, oxygenation and temperature which must occur *in vivo*. The possibility that enzymic systems might alter the course of cholesterol transformation has not yet been adequately explored, but it seems safe to assume a high degree of probability for the occurrence of at least the following substances in the tissues named, if these are supplied with oxygen at a normal mammalian *p*H and temperature:

| Substance | Found in extracts of |
|---|---|
| $\alpha$-7-hydroxycholesterol (II*a*) | ox liver[2], pigs' liver[3], mares' serum[4], pigs' spleen[5]. |
| $\beta$-7-hydroxycholesterol (II*b*) | mares' serum[4], human atheromatous aortas[6]. |
| 7-ketocholesterol (III) | bulls' testis[5]. |
| $\Delta^{3,5}$-7-ketocholestadiene (IV) | pigs' testis[7], pigs' spleen[5], human atheromatous aortas[6]. |
| $\Delta^{4,6}$-3-ketocholestadiene (V) | pigs' spleen[5], human atheromatous aortas[6]. |
| 3($\beta$),5,6(*trans*),-trihydroxycholestane (VI) | ox liver[8], pigs' testis[7], human atheromatous aortas[6]. |
| $\Delta^{4}$-3($\beta$),6,-dihydroxycholestene (VII) | pigs' spleen[5]. |
| 3($\beta$)-hydroxy-6-ketocholestane (VIII) | pigs' spleen[5]. |

Substance (IV) is easily formed in mild conditions by dehydration of (III), and may thus arise during the working-up of extracts. Compounds (II*a*), (III), (IV) and a simple transformation-product of (II*b*) have also been found after 'autoxidation' of cholesterol *in vitro*[1], while (II*a*) and (VII) are obtained when cholesterol is subjected to photo-oxidation[9]. It will be noticed that the transformations indicated by the above substances affect only rings I and II of the sterol nucleus; and in fact no evidence has yet been accumulated which would indicate the course of any more profound breakdown of the molecule. Apart from indirect experiments, such as those of Bloch and Rittenberg with deuterium[10], definite proof of further chemical changes during cholesterol metabolism is still lacking.

It may also be noted that, in spite of the facile *in vitro* production of 7-dehydrocholesterol (IX, provitamin $D_3$), from $\alpha$-7-hydroxycholesterol (II*a*), the mechanism of the formation of this important substance in the animal body remains entirely obscure.

Prelog, Ruzicka and Stein[5] point out that tissues which so far they and their colleagues have examined in great detail differ from adrenal tissues, testis and urine in containing no steroids of the $C_{21}$ (progesterone, corticosterone, etc.) or $C_{19}$ (androsterone, testosterone, etc.) types, a fact which, if it is generally confirmed for other tissues, may prove highly significant for studies of steroid metabolism.

Cholestenone (X) has been found in dogs' and rats' fæces[11] and in pigs' testis[5]. Rosenheim and Webster[11] continue to believe that it is a precursor of fæcal coprosterol (XI), which they think is unlikely to arise, as was formerly believed, by bacterial action in the intestine[12]. The same workers have observed a quite remarkable dietary influence on the production of coprosterol by the intact animal[13]; this discovery may be a valuable lead towards the solution of more than one problem. In this connexion,

it is to be hoped that the saturated sterols so frequently stated to be present in tissues will be re-investigated, especially with regard to their complete chemical identification, since it certainly cannot be stated with confidence that coprosterol itself is absent from the body cells.

Since the above substances (II–VIII) are such as may arise in normal cells during life, it would appear reasonable that they should be tested for physiological activity, especially of the kind which may be directly associated with growth processes.

# OBJECTIVE CLINICAL METHODS

A NEW and remarkably ingenious example of the objective clinical methods which are constantly being developed in modern medicine and surgery is the phono-electrocardioscope designed by Dr. G. E. Donovan (*The Lancet*, 500, April 15, 1944), which permits simultaneous direct visual recording of the phonocardiogram, electrocardiogram and sphygmogram, with amplified auscultation through a binaural stethoscope; in addition, photographic records can be made. The expense of such instruments and the difficulty of producing them in sufficient numbers will prevent all but a few workers from using them, but it is worth remembering that some of them can be applied to the study of the normal animal as well as to the sick animal for whose relief they were invented. The electrocardiograph and the techniques of radiography, cystoscopy and duodenal intubation are examples of objective clinical techniques which can be, and are being, used by anatomists and biologists for studies which have no connexion with disease. The cystoscope or the ophthalmoscope, for example, need not always be used for the study of the bladder or the eye. The principle on which such instruments are constructed can be applied to other things. If an instrument allows you to look into the bladder of a man, it may be used also for seeking out the death watch beetle underneath a floor, and it is being used in this way by Prof. Bayley Butler in Dublin; and the biologist, the medical man and the veterinarian can all use modern methods of studying the fluids and soft tissues of the body and so demonstrate that they are all students in the same field of inquiry.

There will always be, however, an especially close correlation between the methods of the medical man and the veterinarian, because it is their common object to understand and to treat disease—or better, to prevent its occurrence and to maintain health. The trend of medical thought is, or should be, as Prof. J. A. Ryle and other medical men have pointed out (see *Nature*, **153**, 443; 1944), to teach medical students to rely less upon instruments and laboratory procedures and more upon the art of clinical observation and inference in which their grandfathers were so skilled. There will, however, always be some aspects of disease which require the instrument and the laboratory expert. You may be able to diagnose malaria or amœbic dysentery with adequate accuracy by experienced interpretation of the symptoms only, but a protozoologist can do it much more quickly and with absolute certainty; in certain cases, indeed, his laboratory report may be the only means of doing it or of saving the patient's life. In the same way, radiography or the electrocardiograph may give vital information which could not be got in any other way.

The value of such objective methods of study can perhaps be most clearly demonstrated when they are applied to patients who cannot tell the medical man or the veterinarian what their sufferings are. The deaf and dumb adult, the infant and the young child who cannot speak—or, if he can, cannot make reliable statements about himself—must tax to the full the art of the clinician who has only his own experience to guide him. Very often such patients require the aid of objective studies by means of instruments or laboratory procedures which cannot, so the optimist at any rate believes, tell a lie. The neurotic or hysterical adult may also require this

kind of study; and there are some diseases, such as trichiniasis, which are so protean in their manifestations and simulate so many other diseases that the diagnosis can only be made by the finding of the parasite or by serological methods which depend upon considerable laboratory experience. The veterinarian, of course, is always confronted by this kind of difficulty; his patients may be able to utter cries the quality of which may tell the experienced hearer of the vital things, but they cannot tell the whole story, and the experience necessary to interpret them comes only after years of practice. It comes, moreover, only to those who have the ability to acquire it; and it cannot be communicated to students and others except by a similar long experience based on a similar ability.

In a matter like this, the veterinarian and the medical man must therefore find a wide field of mutual interest. It is a field which deserves energetic co-operation and exploration. If the children's doctor may seem to be most likely to profit from such co-operation, the whole of medicine may learn much from the study of animal illness. Comparative medicine, whether it be practised by the medical man or the veterinarian, must certainly have a direct interest in objective methods of study which can give it reliable information about the conditions of certain organs, or about such cardinal symptoms as the quality, intensity and distribution of pain, about normal and pathological variations in body temperature, about fatigue, the reactions of the autonomic nervous system and so on. Much might be learnt, too, from a comparative study of the reactions to certain cardinal symptoms of disease which are shown by animals so different as the carnivore, the ungulate, the mammal and the bird.

The interpretation of the results of studies such as these will not be easy. They will usually involve behaviour patterns for the study of which the co-operation of a psychologist will be required. Perhaps we could begin with a reconsideration of the whole basis of Pavlov's work, or at least with a critical examination of certain criticisms of it (see *British Medical Journal*, 487, Oct. 16, 1943; *ibid.*, 305, Aug. 14, 1943; and *ibid.*, 573, April 22, 1944), which would seem to merit the serious attention of biologists. At any rate, we should have to begin with carefully thought out basic experiments, planned by a medical man, a veterinarian and a psychologist, which would be designed to provide a basis for further work. Such a plan has, in fact, been formulated by the Institute of Animal Behaviour, a committee of which is designing a programme of work the object of which is to explore the possibility of creating an objective science of clinical study. A similar theme was discussed at a recent meeting of the Section of Comparative Medicine of the Royal Society of Medicine. There exists, of course, a great deal of knowledge based on objective experiment which will help such a project; and both the medical man and the veterinarian can supply a vast store of clinical experience which will, if it can be systematized, be invaluable. Meanwhile the explorers stand upon their peak in Darien. Let us wish success to their campaign on behalf of all those, whether they be human or animal, who suffer but cannot tell their sufferings, or, if they would tell, are prevented by their own constitutions or immaturities from telling the truth or directing attention to the root causes of their troubles.

G. LAPAGE.

## THE IMPERIAL CANCER RESEARCH FUND

THE Imperial Cancer Research Fund, which has just issued its forty-first annual report, is still carrying out experimental work and is also improving its financial position. During the past year, more than £20,000 has been added to the capital account, so that the Fund has now almost £430,000 in hand and spends about £15,000 a year in supporting research work in its laboratories at Mill Hill.

With a scientific staff of seven and four visiting workers, the laboratories are working in many fields of cancer research. The visitors include Sir John Ledingham, Dr. L. Dmochowski from Poland and Dr. E. Vasquez-Lopez from Madrid. The report of the director, Dr. W. E. Gye, is divided into sections on carcinogenesis, tissue culture, the mammary tumour inciter, and chemotherapy.

The work on carcinogenesis consists of Mr. H. G. Crabtree's study of the effects on the induction of cancer in mice of substances which inhibit metabolic processes. He has found that organic halogen compounds which react with substances containing sulphur in the body are able to retard the induction of tumours on the skin of mice painted with a carcinogen. The halogen compounds are of two types: those in which the halogen is reactive, as in chloroacetone, and combines directly with sulphydryl groups, and others, such as bromobenzene, which react with sulphur compounds in the body without loss of halogen. Both types of compound appear to cause a local fall in concentration of glutathione when applied to the skin of mice. A similar effect was looked for with maleic anhydride, as it is known that maleic acid combines with glutathione. Maleic anhydride applied to the skin of mice treated with benzpyrene proved to be a more potent inhibitor of carcinogenesis than is bromobenzene. The work suggests that sulphur compounds are connected with the induction of tumours in some way which is not yet clear.

If connective tissue cells are grown in tissue culture in contact with carcinoma cells, the growth of the former is stimulated. On the other hand, sarcoma cells tend to restrain the growth of connective tissue. Stimulating effects of carcinomata have long been known to operate *in vivo*, as the change of connective tissue cells into malignant cells in the presence of transplanted mammary tumours has often been observed. Dr. R. J. Ludford and Miss H. Barlow have tried to demonstrate such a malignant transformation in connective tissue cells grown *in vitro* in contact with mammary cancer tissue, but so far without success.

The effect of the mammary tumour inciter, discovered in the Roscoe B. Jackson Memorial Laboratory in the United States, which is present in the milk of strains of mice with a high incidence of breast cancer, has now been shown to operate in the high-cancer strain *RIII* and the low-cancer strain *S*. It is pointed out that the fact that œstrone treatment induces tumours in male mice of susceptible strains indicates that the factor is present in the tissues as well as in the milk of mice in which mammary cancer occurs. The presence of the inciter in spleen tissue has been confirmed.

The difficulties of work on chemotherapy of cancer are discussed. For effective therapy either all the cancer cells must be destroyed, or the stimulus to divide which is present in these cells must be neutral-

ized. Other difficulties are the similarity in properties of normal and cancer cells, and the variation in growth and lethal effects of spontaneous tumours. The advantages of using a tumour which has arisen in a pure line of mice and is transplanted into mice of the same strain are stressed; no reference is made to a tumour of that nature introduced by Dr. E. Boyland some years ago.

# RESEARCH WORK FOR 1944 IN THE ACADEMY OF SCIENCES OF U.S.S.R.

By LYDIA BACH

THE Academy of Sciences of the U.S.S.R., as the guiding centre for all scientific activity in the Soviet Union, has planned its work for 1944 in four main divisions. First, the study of scientific problems of various branches of knowledge for the advancement of science in general; secondly, research work in the sphere of improving armaments for the Red Army; thirdly, the mobilization of resources to strengthen the defence of the U.S.S.R.; and, fourthly, scientific problems connected with the rehabilitation of regions liberated from the German invaders and devastated by war, and further development of the national economy as a whole.

Plans for the year's work were drawn up by each institute separately, primarily by laboratories and then for institutes as a whole. A committee from each institute selects from its programme problems which offer the greatest interest for inclusion in the general plan of the Academy. Plans are then approved at a general meeting of members of the Academy, corresponding members, and leading scientific workers of each section of the Academy, which examines the subjects submitted in detail and draws up a plan for each section of the Academy. The Academy has eight sections covering the following branches of knowledge: physics and mathematics, chemistry, geology and geography, biology, technology, history and philosophy, economics and law, language and literature.

The 1944 plan which was approved by the presidium of the Academy on December 21, 1943, shows that the Academy is devoting the greatest amount of attention to big theoretical and practical research tasks, on the assumption that other questions can be better dealt with by institutions which work in special spheres and branches of industry.

In the Section of Physics and Mathematics, cosmic rays and the structure of the atomic nucleus will be studied by Dr. A. Alikhanov and Prof. D. Skobeltsin. Expeditions to the Pamirs and Mount Elbrus are being organized to study cosmic rays at high altitudes. The building of a cyclotron has been planned. Dr. P. Kapitza and his colleagues will continue their investigation on properties of matter at temperatures approaching absolute zero. The problems of the structure of matter are being worked at in the Physico-technical Institute by Joffe, and in the Institute of Crystallography by Prof. A. Shubnikov; at the Institute of Physics, S. Vavilov is working on mechanics, luminosity and the employment of luminescence. At the Institute of Mathematics, I. Vinogradov, S. Sobolev, A. Kolmogorov and S. Bernstein are working on theoretical mechanics and giving particular attention to methods of employing calculating machines to solve equations arising in mathematical physics.

In chemistry, work will proceed on the development of modern conceptions of chemical bonds in the kinetics and catalysis of chemical reactions (N. Semenov, Prof. S. Roginsky). Frumkin and his school will continue their work on theoretical questions connected with electrode processes and the theory of surface phenomena. Work on the synthesis of carbon compounds of high molecular weight is proceeding. The chemical institute of the Academy of Sciences is devoting considerable attention to scientific and technical assistance to industrial enterprises, employment of new chemical and technical processes and their intensification, and also the rehabilitation economy of devastated regions which have been liberated from enemy occupation.

The programme for geology and geography includes the study of the main questions of stratigraphy and tectonics of the U.S.S.R., the mineralogy and the geochemistry of the formation and distribution of ore deposits. P. Stepanov will continue his work on the theory of coal formations in the world; V. Obruchev and his colleagues will work on the theoretical and practical problems connected with perpetually frozen territories. The work is being extended to the spheres of hydrogeology and the study of lakes and volcanoes. Work on the study of geography in the Soviet Union and foreign countries, and research work on processes taking place in the soil will be continued.

Each biological institute will work on its own special problems, but will handle them from the evolutionary point of view, developing them all as a complex whole in accordance with the basic problem of biology, that of Darwinism. The institute of evolutionary morphology is studying the laws governing that branch of biology. In the institute of palæontology, Borisyak has established a system of practical phylogenesis for the determination of evolutionary processes in fossils. The institute of physiology (Leon Ordeli) is concerned with the evolutionary processes of various systems of the human organism, muscular, neural, etc. Trofim Lysenko, of the Institute of Genetics, is continuing his work on inheritance.

Work on the humanities includes the study of Russian history, peasantry and working class collectivization, Russian culture, patriotic war, study of Slavonic peoples and the history of international relations. Further volumes, "History, Philosophy", will cover Russian philosophy and the philosophical views of Marx, Engels, Lenin and Stalin.

The mobilization of the country's resources for the needs of defence includes the study of problems connected with the industrialization of Kazakhstan. Work on the oil of new oilfields in Bashkiria continues.

In order to help rehabilitation economy in districts that have been devastated by enemy occupation and by war in general, and to help the general development of national economy, the problem of post-war provision of electrical energy is receiving urgent attention and fundamental principles are being laid down. Research is being done on the restoration of the Donets coal basin and its coalmines; industrial enterprises and transport are being greatly extended. The Academy's institute of economics is working on a very comprehensive publication, "Soviet Economy in the War and Post-War Periods".

## EARLY ASTRONOMY

THE third of the series of articles on early astronomy appearing in *Sky and Telescope*, published in the February issue, deals with the Polynesians (see also *Nature*, April 15, p. 459). In this article it is shown that, contrary to earlier views, these people had an intimate knowledge of the constellations and hundreds of stars. They studied the motions of the planets and the phases of the moon, which were used to indicate lapses of time, and they possessed an extraordinary aptitude for making meteorological forecasts.

In navigation the Polynesians displayed remarkable skill; their method of sailing was usually to steer north or south until they reached the latitude of the chosen island, and then to steer east or west. They made use of the "sacred calabash" for determining the latitude. This consisted of a large gourd in which four holes were bored at the same height near the neck. An accurate horizontal plane was provided by the level of the water at these holes, and a sight through a hole over the opposite edge at a bright star gave the angle of its height above the horizon. By placing the holes at the correct distance below the edge to indicate the latitude of their destination, they knew when to turn east or west to reach the island of their quest. Their long sea journeys proved that the earth was round thousands of years ago.

The Polynesians nearly everywhere commenced the new year on December 1, with the first new moon after the first appearance of the Pleiades in the eastern sky in the evening twilight. In the Hawaiian islands twelve lunar months of thirty days each were used, and the religious year was correlated with the sidereal year by introducing five extra days. The months were divided into three periods of ten days each. The origin of the world was explained by various legends, but some of the fundamental ideas were similar, and a primitive egg was the natural beginning. The darkness of the earth was removed by the raising of the sky and letting in the light of dawn.

In the March issue of *Sky and Telescope* there is a brief reference to the astronomy of the Chinese, Indians, Phœnicians, Greeks and Egyptians. Although the inclination of the ecliptic was determined very accurately by Chou Kung in 1100 B.C., yet this eminent mathematician failed completely in his estimate of the sun's distance, as he calculated from the hypothesis of a flat earth. It is remarkable that, though the Phœnicians were expert navigators, yet they have left no other evidence of their astronomical knowledge.

A few of the attainments of the outstanding astronomers and mathematicians of Greece and Egypt are mentioned in this article, and among these we may refer to Aristarchus of Samos, born in 310 B.C., who attempted to measure the relative distances of the moon and sun by a principle theoretically sound, but beset with practical difficulties which rendered it useless. He assumed that at half-moon the angle at the moon between the directions of the sun and the earth was 90°, and if he could measure the angle subtended at the earth by the lines earth-moon and earth-sun, he could solve the triangle of which one angle was a right angle. Unfortunately, a very small error in either of these angles would be responsible for a considerable error in determining the relative distances of the sun and moon, because the ratio of their distances depends on the small angle at the sun subtended by the earth-moon line, and this angle is very sensitive to errors in either of the other angles. Aristarchus obtained a value of the ratio of the distances of the moon and sun which was about twenty times too great, thus making the sun very close to the earth—about twenty times the moon's distance. Aristarchus had the courage to suggest publicly that the earth was a planet and revolved round the sun like the other planets—a view for which he was charged with impiety.

## THE WHITE BUTTERFLY IN NEW ZEALAND

IN the *New Zealand Journal of Science and Technology* of June 1943, J. Muggeridge, of the Department of Scientific and Industrial Research, gives an account of the introduction of parasites of the small cabbage white butterfly (*Pieris rapæ*) into New Zealand. Two species of parasite are taken into consideration, namely, the Braconid *Apanteles glomeratus* and the Chalcid *Pteromalus puparum*. Following the entry of the same species of white butterfly into North America, the Braconid species just mentioned was introduced from Europe in an effort to obtain a measure of control over the pest in question.

There seems little doubt regarding the soundness of this procedure since the insect is considered to be one of the most important agents destroying the caterpillars in North America to-day. This conclusion naturally suggested the possibility that the Apanteles would similarly parasitize, and so destroy, the caterpillars of the butterfly in New Zealand. Acting on these foundations, upwards of half a million cocoons of the Apanteles were introduced from England into New Zealand during the years 1931–34. Liberations were made in various localities, but in spite of intensive field surveys the creature appears to be no longer present.

During 1938–39 about six thousand American-bred Apanteles were introduced, and all the evidence indicates that these have become successfully established. The behaviour of the European *Apanteles glomeratus* contrasts sharply, therefore, with that of the American-bred form. The Pteromalus is a parasite of the pupa of the butterfly. Its larva kills the pupa and the adult Chalcid emerges through a small hole made in or near the region of the wing of the future butterfly. The male Chalcids remain near the pupæ from which they have issued and wait there for the appearance of the females with which they mate. This parasite was sent to New Zealand while still within the pupæ of the butterfly and was first introduced during 1932–33 when about five hundred of these chrysalides were shipped. From out of these hosts more than twelve thousand adult parasites emerged and nearly nine thousand were liberated in the field in 1933. From a field survey made at the latter end of the same season it was found that out of 415 collected butterfly pupæ 58 per cent had become parasitized. The species thus became established with remarkable rapidity and is exercising a useful degree of control. As the author remarks, it has spread rapidly from the points where liberations were originally made, even as far as eighty miles in the first season, and it has had a marked influence in reducing the butterfly population and the damage

caused by the caterpillars. It has been found to be extremely efficient under dry conditions, where the bulk of the Cruciferous crop is grown, but in places with a high rainfall the butterfly seems better able to live than the parasite. It is suggested that this seeming failure might be offset by the introduction of some other larval parasite and one better fitted to withstand the conditions in such areas.

## FORTHCOMING EVENTS

### Saturday, July 1

INSTITUTE OF PHYSICS (LONDON AND HOME COUNTIES' BRANCH) (in the Physics Department, Imperial College of Science and Technology, South Kensington, London, S.W.7), at 2 p.m.—Conference on "Applied Spectroscopy". (Prof. H. Dingle: Introductory Address; Mr. F. Twyman, F.R.S.: "Spectroscopic Instruments"; Mr. D. M. Smith: "Spectrographic Analysis"; Dr. W. A. Roach: "The Determination of Mineral Deficiencies and Excesses in Plants by Spectrographic Analysis"; Dr. R. W. B. Pearse: "Applications of Molecular Spectra").

### Monday, July 3

ASSOCIATION OF AUSTRIAN ENGINEERS, CHEMISTS AND SCIENTIFIC WORKERS IN GREAT BRITAIN (at the Austrian Centre, 69 Eton Avenue, Hampstead, London, N.W.3), at 7.30 p.m.—Dr. I. Broda: "Prominent Austrian Scientists".

### Tuesday, July 4

ROYAL SOCIETY OF MEDICINE (at 1 Wimpole Street, London, W.1), at 2 p.m.—Colonel Prof. A. T. Jurasz: "Former and Post-War Health Problems in Poland" (Lloyd Roberts Lecture).

### Friday, July 7

ROYAL ANTHROPOLOGICAL INSTITUTE (joint meeting with the INTERNATIONAL AFRICAN INSTITUTE) (at 21 Bedford Square, London, W.C.1), at 1.30 p.m.—Mr. P. P. Howell: "The Installation of the Shilluk King".

GEOLOGISTS' ASSOCIATION (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. Maurice Black: "Limestone Depositions in the Bahamas".

### Thursday, July 6—Sunday, July 9

BRITISH RHEOLOGISTS' CLUB (at St. Hilda's College, Oxford).—Conference.

**Friday, July 7**

10 a.m.—"Rheology of Large Deformations and Plastic Flow", (a) Plasticity of Metals; (b) Polymers; (c) The Liquid State.

2.15 p.m.—"Relations between Shear, Tension and Compression in Complex Bodies (The pi-problem)".

5 p.m.—"Some Rheological Applications to Medical Science".

**Saturday, July 8**

10 a.m.—"Rheological Nomenclature and Symbols Metallurgical and Non-Metallurgical".

8.30 p.m.—"Future Organisation of Rheology".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT MASTER (full-time, graduate preferred) to teach mainly MATHEMATICS and SCIENCE in the Junior Building School of the Accrington Technical School—The Director of Education, Broadway Chambers, Accrington (July 4).

CIVIL ENGINEER as Chief of Construction Department with an Oilfield Company in Peru—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. E.1010XA) (July 5).

ELECTRICAL INSPECTOR OF FACTORIES (temporary) in the North-West of England—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. D.798A) (July 5).

SENIOR ASSISTANT DRAINAGE AND IRRIGATION ENGINEER (Reference No. E.902A), and a JUNIOR ASSISTANT DRAINAGE AND IRRIGATION ENGINEER (Reference No. E.903A), by the Sierra Leone Government —The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting appropriate Reference No.) (July 5).

EXECUTIVE ENGINEER by the Sierra Leone Government—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. E.1011A) (July 5).

SPEECH THERAPIST (full-time, temporary)—The Director of Education, Education Offices, 14 Sir Thomas Street, Liverpool (July 7).

TEACHER OF ENGINEERING SCIENCE AND MATHEMATICS, and a TEACHER OF ELECTRICAL ENGINEERING, SCIENCE AND MATHEMATICS in the Bootle Municipal Technical College—The Director of Education, Town Hall, Bootle (July 7).

LECTURER (full-time) IN THE DEPARTMENT OF MECHANICAL ENGINEERING—The Principal, Derby Technical College, Normanton Road, Derby (July 8).

SPEECH THERAPIST to the St. Helens and Wigan Education Committees—The Director of Education, Education Office, St. Helens, Lancs. (July 8).

TEACHER (full-time) IN TEXTILES in the Oldham Municipal Technical College—The Director of Education, Education Offices, Oldham (July 8).

TECHNICAL CHEMIST (Reference No. F.2012XA), and a LABORATORY ASSISTANT (Reference No. F.2503XA), by London Paint Manufacturers —The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting appropriate Reference No.) (July 8).

LECTURER (full-time) IN PHYSICS—The Principal, Royal Technical College, Salford (July 10).

AGRICULTURAL ENGINEER for the Ceylon Government Department of Agriculture—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2189A) (July 10).

ASSISTANT VETERINARY INVESTIGATION OFFICER at the Agricultural Advisory Centre—The Secretary and Registrar, The University, Bristol (July 14).

PSYCHIATRIST (part-time, man or woman), an EDUCATIONAL PSYCHOLOGIST (woman), and a PSYCHIATRIC SOCIAL WORKER (woman), in the Child Guidance Service in the North Riding—The Secretary, Education Offices, County Hall, Northallerton (July 15).

SPEECH THERAPIST—The Director of Education, Shire Hall, Nottingham (July 15).

ASSISTANT LECTURER AND DEMONSTRATOR (woman) IN ZOOLOGY—The Principal, Royal Holloway College, Englefield Green, Surrey (July 15).

DEMONSTRATOR (man or woman) IN THE DEPARTMENT OF INORGANIC AND PHYSICAL CHEMISTRY—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1 (July 17).

CHEMISTS (temporary) with considerable experience in analysis of metals—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. F.2628A) (July 25).

LECTURER IN EXPERIMENTAL PHYSIOLOGY—The Registrar, The University, Sheffield (July 28).

ASSISTANT SECRETARY to the Oxford and Cambridge Schools Examination Board—The Chairman of the Oxford Delegacy, St. Catherine's Building, St. Aldate's, Oxford (July 31).

READERSHIP IN PHYSICAL ANTHROPOLOGY—The Registrar, University Registry, Oxford (August 31).

MISTRESS TO TEACH BIOLOGY AND GENERAL SCIENCE in the Day Technical School for Girls and the Day Technical School for Boys, a TEACHER OF ENGINEERING SUBJECTS, and a MATHEMATICS MASTER —The Principal, Technical Institute, Gravesend.

LECTURER (full-time) IN ENGINEERING SUBJECTS in the South-East London Technical Institute, Lewisham Way, London, S.E.4—The Education Officer (T.1), County Hall, Westminster Bridge, London, S.E.1.

TECHNICAL ASSISTANT (male or female) for abstracting and preparing bibliographies and summaries of technical articles mainly in Electrical Engineering and Applied Physics—British Electrical and Allied Industries Research Association, 15 Savoy Street, London, W.C.2.

# THE APPROACH TO FULL EMPLOYMENT

THE publication of the White Paper on Employment Policy almost on the eve of the launching of the invasion to liberate the peoples of occupied Europe was an imaginative stroke. It has both strengthened confidence in the determination of the Government to pursue resolutely a policy which will effectively implement its declared aim of maintaining a high and stable level of employment after the War, and fortified the nation for whatever may be demanded of it in the weeks that lie immediately ahead. More, it represents not merely a new departure in Government policy and an example of real leadership, but also, in some respects, the shaping of policy in accordance with scientific principles. To the fundamental statements and principles set forth in the report there can be little or no exception. Opinions may indeed differ as to the methods by which particular points of policy are to be implemented, and as to whether those which the Government proposes to use in the first instance are likely to be effective enough, or put into practice with sufficient firmness. Beyond this, however, a great merit of the statement is that it makes unmistakably plain, while acknowledging the Government's responsibilities in the matter of policy and decision, that there are limits beyond which Government action cannot go, and that the success of an employment policy must depend very largely on the understanding and support of the community as a whole. Whether or not the Government could do more than is indicated in this statement to promote a rising standard of industrial efficiency, such action could not be effective without corresponding efforts from both employers and workers. Without such co-operation, even measures already proposed by the Government may be frustrated of their purpose.

If for nothing else, this statement therefore is to be welcomed for its educational value. In the problems of the transition from war to peace—such as demobilization, the necessity for continuing war-time controls, the transfer of workers, their re-training and other measures to increase their mobility—the position is lucidly explained and reasons are given which should go far to assist in gaining public assent and co-operation in proposals which may to some extent be unpalatable and involve a break with professional or trade custom or practice. The necessity of explaining policy and measures in advance has been repeatedly urged in connexion with demobilization and like problems, notably in a valuable report, "The Organization of Employment in the Transition from War to Peace", submitted to the International Labour Conference at Philadelphia, and the White Paper is fully in keeping with the recommendations and spirit of that report. Any demobilization scheme finally agreed upon should be clearly understood by the people and the interests affected by it. If, as the report observes, the scheme is widely discussed, and if, after discussion, it is accepted as fair and reasonable, then some of the pressures apt to cause disorderly mobilization can be relieved or abolished.

Again, not only is it a matter of winning public approval of what is involved in policy. The Government also recognizes that, in its proposals for extending State control over the volume of employment, it is entering a field where theory can only be applied to practical issues with confidence and certainty when experience accumulates and experiment extends over untried ground. It is intended, therefore, to establish on a permanent basis a small central staff qualified to measure and analyse economic trends, and to submit appreciations of those trends to the Ministers concerned. It is also vital for the Government to obtain, more fully and much more quickly than in the past, exact quantitative information about current economic movements, and the Government appeals to industry for co-operation in this task. Only industry can provide the statistical information required, and only a central authority can classify and analyse information drawn from the country as a whole.

In this respect the White Paper points out that the efficient operation of an employment policy will require statistics of employment and unemployment, including quarterly or monthly statements of present and prospective employment in the main industries and areas of Great Britain, based on returns from employers, as well as regular information relating to savings, projected capital expenditure by public authorities, and, so far as possible, by private industry. An annual census of production showing the structure of the main groups of industries in the preceding year, including, *inter alia*, details of the quantity and value of output, stocks, and work in progress, together with monthly figures of production, consumption and stocks, and, if possible, figures of orders on hand, based on sample returns obtained periodically throughout the year from large firms, trade associations and public institutions, must also be provided. The Government has already repeatedly affirmed its intention of extending the provision of official statistics after the War, and it is now stated that the annual White Paper on National Income and Expenditure is to be developed by providing a much more complete analysis of the constituent parts of the country's total expenditure.

This central analysis of our financial position, which will be subject to continuous review and adjustment throughout the year, will serve as a basis for determining what measures are required to maintain employment and secure a rising standard of living. Parallel studies, at every stage, of the man-power situation will be undertaken by the Ministry of Labour and National Service, and these surveys will indicate the probable supply of labour over the coming period, the prospective changes in employment in the different industries, and the effects upon employment of Government projects designed to modify the volume of investment or expenditure. The correlation of these complementary budgets—for total expenditure and for man-power—will play a vital part in the formulation of Government policy for the maintenance of employment.

The debates on the Budget will in future provide an annual opportunity for Parliament to review the financial and economic health of Great Britain as a whole, and to consider the prospects for the coming year. This step may be regarded as part of the programme of educating the country as to what is required in a policy of employment which at the same time aims at securing for the nation the most effective use both of its man-power and of its material resources. Measures to increase total expenditure at the onset of a depression will no doubt be welcome; but the restraining measures appropriate to a boom may meet with opposition unless they are seen and understood as part of a continuing policy for maintaining employment, and accepted as the price that must be paid for the success of that policy over a long period.

It is right that we should turn first to the measures by which the Government seeks to provide itself with the instruments for giving effect to policy in this field, for unless the appropriate instruments are available and the basic data accumulated in readiness, the right decisions and the appropriate policy may not be determined or effectively put into operation. The White Paper, however, shows that in breaking new ground in regard to policy, the Government is providing itself with exactly the instruments required for the formulation of policy for which scientific workers have long pressed. No point, in fact, was more strongly urged in the Barlow Report, for example, than the necessity for more fact-finding machinery in regard to the location of industry and the natural resources that might be affected by industrial location, and the Commission was unanimous in recommending that the functions of the new national authority proposed should include the collection and co-ordination of such information.

Whether the instruments proposed by the Government will in fact prove adequate remains to be seen, and can scarcely be judged until the fuller proposals on particular points are made known. In regard to the collection of statistics, some further organization more on the lines of that recommended by the Council of the Royal Statistical Society in its Memorandum on Official Statistics (see *Nature*, **153**, 88; 1944) may prove necessary; this may indeed be contemplated by the Government, although it is not explicitly mentioned in the White Paper. The provision of statistics cannot be left to returns supplied by industry itself alone, however important the co-operation of industry may be. Nevertheless, it is clear that we have something more of a scientific approach to questions of public policy.

Turning now to the question of policy, the White Paper visualizes some ten different methods by which the Government may influence employment in furtherance of its objective. First, there is the action to be taken in the period of transition from war to peace, to avoid the threefold danger that patches of unemployment may develop where the industrial system fails to adapt itself quickly enough to peace-time production; that demand may outrun supply and create an inflationary rise in prices; and that civilian production, when it is resumed, may concentrate on the wrong things from the point of view of national needs. It is clear from the White Paper

that the Government is fully alive to these dangers; it will be recalled that the report presented to the Philadelphia Conference directed attention to them, as did also an admirable study issued last year by the League of Nations Delegation on Economic Depressions (see *Nature*, **152**, 365; 1943). In regard to the first, plans are being worked out to promote the orderly expansion of peace-time industries throughout the transition period by assisting firms to switch over their capacity to peace-time production as quickly as possible, by finding out in advance where the skilled labour which will gradually become available will be most urgently required, and by arranging, so far as war conditions permit, that labour and raw materials will be forthcoming for urgent civilian work. Steps are being taken to ensure that the machinery of allocation devised in war-time will be adaptable to the special conditions likely to obtain after the end of the War in Europe. Curtailments of munitions production will be made first in areas where the capacity and labour can be used for civilian products of high priority. The disposal of surplus Government stocks will not be allowed to prejudice the re-establishment and development of the normal trade channels for producing and distributing similar goods; and the disposal of Government factories will be regulated so as to help towards the early restoration of employment.

In regard to the second danger, the White Paper insists on the need for public support for such measures as the continuance of rationing and a measure of price control; but it is emphasized that there is no intention of maintaining war-time restrictions for restriction's sake. Some controls there must be; the habit of saving must still be encouraged, though, as Lieut.-Colonel K. E. Edgeworth points out in his book, "Unemployment Can Be Cured" (see p. 40 of this issue), the vital question is how much saving: over-saving can create unemployment. There must be discipline and imagination in peace no less than in war, and nothing will so speedily ensure that the peace is lost as the same craving for indulgence in an easy peace that we yielded to in 1918–20. Again, to avert the third danger it will be necessary to establish certain broad priorities, and to enforce them for a time by means of the issue of licences, the allocation of raw materials and a measure of control over the labour and staff required for industry.

The reasons for all these measures are well put in the White Paper, and this is equally true of the second field, namely, those concerned with the expansion of our external trade, by the creation, through collaboration with other nations, of the conditions of international trade which will make it possible for all countries to pursue policies of full employment to their mutual advantage. Here again the White Paper emphasizes that it is with industry that the responsibility and initiative must rest for making the most of opportunities to recover export markets and to find fresh outlets for products. While this is true, there is a slight tendency to discount the full measure of Government responsibility for securing the conditions in which such expansion can best be promoted, and a like comment might be made on the White Paper's observations on the promotion of industrial efficiency. There is a disposition to regard recent taxation concessions in regard to research and obsolescence as a sufficient contribution; more may well be expected of the Government in this respect than is indicated. The promotion of industrial efficiency is a matter of paramount importance that must be kept under constant review, and further measures will almost certainly be required.

A whole chapter of the White Paper is devoted to the fourth series of measures, namely, those designed to secure the balanced distribution of industry and labour; and this has already been the subject of a debate in the House of Commons, in which attention was once again directed to the Barlow Report. Dealing first with the problems of local unemployment as presented in the 'distressed' or 'special' areas, Mr. Dalton, president of the Board of Trade, said that it is proposed to discontinue the use of these terms; these areas will in future be known as 'development areas'. The Government proposes to attack these problems in three ways: first, by so influencing the location of new enterprises as to diversify the industrial composition of areas which are particularly vulnerable to unemployment; secondly, by removing obstacles to the transfer of workers from one area to another, and from one occupation to another; and thirdly, by providing training facilities to fit workers from declining industries for jobs in expanding industries.

Mr. Dalton's speech showed that the Government's policy for the location of industry goes a good deal further than is indicated in the White Paper itself. Mr. Dalton stated that the Government has now explicitly accepted the two main ideas of the Barlow Report, namely, the spreading out of the very congested areas over wider areas, and the encouragement of a reasonable balance of industrial development as between the various regions in Great Britain and the suitable diversification of industry within each region. Mr. Dalton was at pains to point out that the Government is already in possession of powers to enable it to exercise a substantial influence over the location of new industrial development, both to prohibit the establishment of a new factory in a district where serious disadvantage would arise from further industrial development, and to steer new factory development into areas which call most urgently for further industrial diversification. It is clear, however, from the debate, that Mr. Dalton was unable to convince the House of Commons that the Government is in earnest in this matter, or that without new powers, it is able to implement the policy disclosed even in the White Paper.

Sufficient reason for such scepticism may well be found in the simple fact that the fundamental recommendation of the Barlow Report—the establishment of a central planning authority, whether advisory as recommended by the majority, or executive as recommended by the minority—is ignored. Mr. Dalton, in indicating his support of the minority proposal, suggested that the required department exists in the Ministry of Town and Country Planning. This

suggestion will satisfy no one who appreciates the importance of a definite policy for the utilization of the land. The location of industry cannot be guided without planning the use of land. The Ministry of Town and Country Planning is neither equipped nor authorized to carry out the function of the central planning authority visualized unanimously by the Barlow Commission as extending far beyond the powers of any Government department then existing, and extending to "continued and further redevelopment of congested urban areas where necessary ; decentralization or dispersal, both of industries and industrial population, from such areas ; and encouragement of a reasonable balance of industrial development—coupled with appropriate diversification of industry in each division or region throughout the country". The Ministry, it should be remembered, represents not an accretion of new departmental power, but an aggregation of powers and functions from existing departments, and we need look no further than to the history of the Butlin proposal to establish a holiday camp on the Lleyn peninsula for an apt illustration of the limitations of its present powers.

The same chapter of the White Paper covers a further method which the Government also intends to use. The mobility of labour is an important factor both in reducing the dislocation which arises from changes in technique and fluctuations in market conditions, and also in ensuring that the expansion of new industries under the stimulus of a high level of demand is not hampered by a shortage of skilled labour. Such mobility is an essential feature of a full employment policy, but it by no means involves of necessity the large-scale transfer of population, and it seems clear from the White Paper and from the debate that such transference is not contemplated by the Government. Some geographical flexibility and mobility there must be, but much more important is mobility of skill, and the readiness and capacity to transfer from one occupation to another. That was the point on which Mr. G. H. D. Cole insisted in his Mather Lecture to the Textile Institute, and the acquisition of at any rate two kinds of skills should be an objective in the policy of technical education which, in view of its bearing on industrial efficiency, must be a counterpart to any employment policy.

These five methods directly concern many scientific workers. The remaining five, though more of indirect interest, may well prove even more important in ensuring the success of an employment policy. Put briefly, they may be described as the stabilization of private investment, public works, the maintenance of consumer purchasing power, the stabilization of prices and wages, and the discouragement of restrictive practices. In regard to the maintenance of total expenditure the White Paper sets forth as the guiding principles of the Government's policy, first an increase in exports ; secondly, the limitation, so far as possible, of dangerous savings in expenditure on private investment ; thirdly, the careful planning of public investment both in timing and in volume to offset unavoidable fluctuations in private investment ; and lastly, readiness to check and reverse the decline in expenditure on consumers' goods which normally follows as a secondary reaction to a decline in private investment.

One scheme contemplated by the Government when the abnormal conditions of the immediate post-war years have disappeared is for varying social insurance contributions in accordance with a forecast of the average level of unemployment, the rate of contribution actually levied increasing when unemployment falls below the estimated average level and decreasing when unemployment exceeds that level.

In regard to restrictive practices, the White Paper contains warnings both to employers and to workers. An undue increase in prices due to causes other than increased wages might frustrate action taken by the Government to maintain employment ; for example, if additional money made available by the Government to maintain employment were absorbed in increased profit margins through the formation of a ring by the manufacturers in a particular industry for the purpose of raising prices, and no increase in employment resulted. Trade union practices and customs may equally constitute a serious impediment to an expansionist economy and so defeat the object of a full employment programme ; and they, too, must be examined by workers themselves. There is a note struck here which professional associations of scientific workers will do well to heed, for no professional association long remains altogether free from a restrictionist outlook, which may be at issue with the public interest. Nothing is healthier in the White Paper than this appeal to put the public interest before sectional interest or advantage, and to tolerate no arrangements which obstruct or impede public policy. It is on the response to this appeal that we may best found our hopes of the success of an employment policy.

Critics have already pointed out that the policy outlined in the White Paper is not, except perhaps so far as the transition period from war to peace is concerned, a policy of full employment. It does not propose positive steps to provide jobs at all times for all workers by ensuring that the real needs of the people for housing, health, education and good living are met continuously, to the exclusion, if need be, of demands for less essential things. Much will depend on the other measures in the Government's reconstruction programme, notably on the social security proposals and those for dealing with the use of the land, and the problems of compensation and betterment considered by the Uthwatt Committee.

None the less, the welcome given to the Government's proposal in the three-day debate in the House of Commons to create an economic general staff is a sign of a new approach to the problem of employment and of a realization of the importance of a factual basis for policy. The criticism launched at the White Paper in the debate should dispel any false ideas or extravagant hopes: the means by which rising wages are to be linked with increased productivity are yet to be delineated. The emphasis was placed on the promotion of industrial efficiency, and Sir John Anderson stressed the need for

developing a new technique of control to cover both privately and publicly owned industry.

The White Paper thus outlines a policy which merits the serious attention not merely of the specialist but also of the ordinary citizen, as a further step towards a scientific approach to some of our major economic problems. But no measures put into operation to implement that policy will have their full effect without the co-operation and intelligent support of the whole community. This can come only through full debate and discussion, whereby the country can be fully educated as to the magnitude of the issues and the extent to which co-operation and acceptance of restraints may be required of every individual.

## SCIENCE AND BROADCASTING

### Reshaping Man's Heritage

Biology in the Service of Man. By J. S. Huxley, H. G. Wells, J. B. S. Haldane, W. G. Ogg, J. C. Drummond and W. F. Crick, J. W. Munro and J. Fisher, W. H. Kauntze, L. J. Witts, Major P. G. Edge, J. M. Mackintosh, Sir E. V. Appleton. Pp. 96+7 plates. (London: George Allen and Unwin, Ltd., 1944.) 5*s*. net.

"RESHAPING MAN'S HERITAGE" comprises a series of talks which were broadcast round the theme that, by the use of science, man is achieving greater freedom as well as surer control of his heritage. The series was introduced by H. G. Wells, who spoke about man's accomplishments, opportunities and pitfalls. The other contributors are specified under the title-heading above and their talks included such subjects as man's food, the good earth, reshaping plants and animals, the conquest of the germ, the banishment of pain, and preventive medicine.

Of the talks themselves little need be said. The subjects were chosen carefully, the whole group was well co-ordinated, and the names of the distinguished persons who gave the talks lent sufficient appeal to attract the mass of listeners for whom they were intended. Further, the language used by the speakers was sufficiently clear and non-technical to make the presentation one that should not have taxed any listener unversed in science.

Yet this group of broadcasts raises a problem which will need close attention by men of science. The present writer was privileged to arrange the series as material for an army listening group. The men and women who attended were mostly of a fair standard of education and intelligence, and, although their knowledge of science was limited, attended the broadcasts voluntarily. What were their reactions? It cannot be said that the interest of the Service men and women was aroused to any extent or that they were highly stimulated. In the main the talks were borne patiently, and little animation developed. It was difficult to find out why the majority of talks did not attract, but experience with other army groups may help to throw some light on the matter.

Since the War-Time Army Education Scheme was introduced in 1940, many thousands of talks and lectures have been given to troops on all kinds of 'educational' topics. Those which have been outstandingly successful have been derived from personal experiences of the speaker—travel, exploration, particular employment, etc. (The talk in this series on the control of rats reminds one of the broadcast some months ago by a Cockney rat-catcher on how to trap rats. His methods may not necessarily have been the most successful ones, but troops are still discussing the talk.) Talks which have met with least response have been those which the audiences consider to be academic and detached from their lives. Here lies the crux of the problem.

If we wish to interest the masses in the impact of science on society—we assume that the person who arranged this series of elementary talks wished to interest as many listeners as possible—we must first recognize that the ordinary man and woman only too often regard science as academic and aloof, and are not infrequently a little afraid of it. It is essential, therefore, when planning a programme of popular science talks, to ensure that the subjects chosen fall within the daily interest of the listener. On this score alone, the series under discussion could have been little improved upon. The fault, if fault there be, lay with the presentation.

The time is long overdue when men of science, among others, began to learn of the effect which their discoveries have made, and are making, on the masses of the people. One shilling will produce a comfortable seat 'at the pictures' where education can be absorbed pleasantly and without physical and mental exertion. A third of a shilling will produce a weekly journal where the many photographs are seductively displayed and unencumbered by much wearisome reading matter. These—and others—are the educative rods which inventive man has made for his own back.

How can these opiate effects be combated? It is not enough merely to say that we must raise the standard of films or give John Citizen more information on how or what to read. We must also use the weapons available now and help John Citizen to want to raise the standards himself. Broadcasting is one of the tools. But we must attend to presentation. In this connexion we may take a hint from the Schools Broadcasting Department. When a particular broadcast is being prepared, as much time is given to the way in which a topic is to be 'put over' as to the subject-matter itself. Straight talks, even of fifteen minutes duration, are seldom given. The appeal of different voices has been recognized and the question-answer or discussion method between two or more people is frequently used. (Of the twelve broadcasts under the heading of "Reshaping Man's Heritage", ten were straight talks; two consisted of dialogue conversation.) Again, when a straight talk is given, much more attention is paid to the speaker's degree of 'mike-worthiness' than is the case with the Adults Talks Department of the B.B.C. That a man or woman is an authority on a particular subject is not enough to make him a good broadcaster. He should have a microphone manner which will appeal to the largest body of listeners and make them want to listen again to the broadcast of a related subject. With the exception of two, and possibly three, of the speakers in "Reshaping Man's Heritage", how many succeeded in making the listeners anxious to obtain further information about these all-important issues?

It may rightly be argued that there are few men—and less women—who are expert in a particular field and yet naturally have a microphone personality which is acceptable to the majority of listeners.

It is a remarkable fact that the number of first-rate broadcasters on any special subject number less than half a dozen. How, then, can science topics be presented to make the appeal which they inherently possess for the bulk of the population ?

One of the answers lies in the greater use of feature programmes. Script-writers of the calibre of Louis MacNiece would have made any of the topics of "Reshaping Man's Heritage" so attractive that many more listeners would have been attracted. It is not suggested that straight talks be eliminated from broadcasting. Great names are themselves an attraction and many people listen at first not for the subject-matter but because Dr. So-and-So is broadcasting. But when Dr. So-and-So is the authority on a particular subject which lends itself to broadcasting and he is not suitable either in manner or personality to make the subject attractive over the microphone—this was even more evident in the recent series "Science at Your Service" than in "Reshaping Man's Heritage"—he might well be asked to prepare a script which could be presented in 'feature' form by skilled broadcasters. To soften criticism on this point, perhaps it is worth mentioning that the B.B.C. has a maxim, developed from experience, that to make a broadcast sound natural it must be 'staged'. Examples of this are constantly being referred to by W. E. Williams in his sagacious column called "The Spoken Word" which appears each week in *The Listener*.

This brings the discussion to its focus. The B.B.C. should have on its directing staff a man of science of the standing of the co-ordinator of "Reshaping Man's Heritage". He should be instructed to develop the place of science in broadcasting and to use the necessary discrimination in the selection—and rejection—of speakers. He should be given a staff whose duty it would be to investigate the various methods of making scientific broadcasts attractive.

In conclusion, it should be said that "Reshaping Man's Heritage" makes good reading for the elementary student wishing to extend his knowledge of the application of biological research to human welfare.

T. H. HAWKINS.

## CONTROL OF UNEMPLOYMENT

**Unemployment Can Be Cured**

By Lt.-Col. K. E. Edgeworth. Pp. 158. (Dublin: Eason and Son, Ltd.; London: Simpkin Marshall, Ltd., 1944.) 10*s*. 6*d*.

THE conclusions and suggestions put forward by Colonel Edgeworth in this book run closely parallel with the policy set out in the White Paper on Employment Policy. The four serious types of unemployment which Colonel Edgeworth considers need handling are all recognized in the official statement, and the measures he advocates find a place in the Government's policy.

First, for example, there is unemployment caused by fluctuations in the demand for industrial equipment and for buildings, to be remedied by a certain measure of national planning and control over the volume of output. This control, Colonel Edgeworth suggests, might be, as suggested in the White Paper, in part voluntary, assisted and supplemented by an appropriate control of Government expenditure. Secondly, there is unemployment caused by the decline of existing industries owing to the development of new industries of greater technical efficiency. For this the remedy is to facilitate the transfer of the displaced workers to other occupations, the scheme including the cost of training and the payment of wages or part wages during the period of transition. Co-ordination of such transference with plans for the development of housing and for the expansion and location of new industries would also be required.

Thirdly, unemployment is caused by the decline in purchasing power which arises from over-saving. This is the distinctive feature of Colonel Edgeworth's book, where the influence of this factor is worked out in considerable detail and with some approximation to quantitative computation. Fourthly, unemployment is caused, especially in the smaller countries, by the competition of larger and more efficient industries abroad. Apart from this, Colonel Edgeworth just touches on the question of agriculture, to which the White Paper makes only passing reference. Schemes for sustaining agricultural prices by increasing the bargaining power of the farmer in marketing his surplus, national schemes for storing the surplus output of exceptionally good years, and some international planning in respect of international purchases of agricultural products, are among the measures he advocates for securing a healthy and well-balanced agriculture.

Colonel Edgeworth's analysis leads him to conclude that individual saving should not exceed 3 per cent of the national income, and that it can be kept down to this figure by a suitable system of taxation and death duties. Business saving tends to increase with undesirable rapidity when trade expands, and acts as a brake on expansion, preventing the attainment of full employment. To provide the remedy of passing on to the consumer, in the form of reduced prices, the reduced costs which are associated with expanding output, he suggests that the boards of management of all large business enterprises should include representatives of workers and consumers to see that this principle is observed. The volume of Government saving should be determined by the opportunities for utilizing the money in an investment worth while, and if other means of controlling the surplus saving prove inadequate, he suggests that the Government should borrow the surplus savings and expend them on social services, rather than on public works. This is in effect what the White Paper suggests in the differential scheme of contributions to social insurance.

With regard to international trade, Colonel Edgeworth suggests a combination of moderate tariffs with a system of price control through the control of wages and associated with the control of profits. Here he appears to go somewhat beyond the measures the Government is at present prepared to contemplate; but he recognizes that the smooth working of any such scheme will depend very largely on how far each country is prepared to accept the principle that a properly adjusted system of international trade is to everybody's advantage, and that it can only be secured by mutual co-operation.

There can be no question as to the value of Colonel Edgeworth's little book as a stimulant to public interest in these problems and as an indirect comment on Government policy as outlined in the White Paper. It should provoke further discussion on the causes of unemployment and assist to clarify the issues, whether or not the remedies he suggests be regarded as appropriate.

# THE GALACTIC SYSTEM*

By SIR JAMES JEANS, O.M., F.R.S.

THERE is a promontory on Mount Wilson from which the visitor to the Observatory can look down at night and see the lights of Pasadena and Los Angeles on the plain 7,000 ft. below. He cannot distinguish individual lights, but sees two patches of luminosity which indicate the outlines of the cities and the distribution of density—if not of population, at least of the street-lights. It is so easy to study this distribution from up here, and so difficult from inside the cities, where one cannot see the forest for the trees.

This is, of course, an astronomical parable. In the night sky we see a number of distinct stars, and also a far greater number which are merged into the continuous band of light we call the Milky Way. These together constitute the galactic system—the city of stars in which we reside. But far out beyond this we see objects of another kind—the extra-galactic nebulæ—which we believe to be other cities of stars, external to our own.

It is easy to study the distribution of light, and so of stars, in these external galaxies; we need only take a photograph or, better, photometric measurements, and the thing is done. But our own galaxy presents problems of an entirely higher order of difficulty.

If the stars were distributed uniformly through infinite space, the number in a sphere of any size would, of course, be proportional to the cube of the radius of the sphere, and this would lead to the simple law that vision down to stars of one magnitude fainter would increase the number of stars which could be seen fourfold. If the uniform distribution of the stars fell off after a certain distance, this distance would be revealed by the failure of this law. Using this method, the two Herschels studied the distribution of the stars in space, and were led to picture the galactic system of stars as a flat disk, the plane of the Milky Way being, of course, the plane of the disk. This plane is observed to divide our sky into exactly equal halves, and the sky looks about equally bright in all directions in it; whence the Herschels concluded that we are close to the centre of the disk.

At a later date, the globular clusters seemed to tell a different story. These are compact clusters of millions of stars, all being very similar in appearance. So far back as 1911, A. R. Hinks had noticed that they all lie in one half of the sky. A detailed study by Shapley confirmed this—nearly all lie within a range of 130° of galactic longitude. Cepheid variables abound in the clusters, so that their distances are easily measured, and Shapley could map out the distribution of the clusters in space. He found that all except one—possibly a stray—lie in or near a circle of about 100,000 light-years radius, in the galactic plane. But the sun is not at or near the centre of this circle; it is about 40,000 light-years distant. It was natural to think that the boundary of this system of clusters must mark out the limits of the galaxy, but it seemed strange at the time that this did not coincide with the boundary of the visible stars.

The discovery that space is filled with obscuring matter has now removed this difficulty, and brought all the elements of the problem into harmony. Observation shows that this obscuring matter makes a fog of which the density varies greatly in the different parts of space. As might be expected, it is densest in the galactic plane; here a beam of light is halved in intensity after traversing about 3,000 light-years of distance. Thus the range of visibility in the fog is not a very great number of thousands of light-years. The Herschels, and many after them, who did not know of the fog, mistook the range of visibility in the fog for the radius of the galaxy. This is why we seemed to live at the centre of things; for in a fog, we each have our own sphere of vision, of which we are always at the centre.

The figure just mentioned shows that the fog reduces light to a ten-thousandth part of its original intensity in travelling from the centre of the galactic system to the sun. Thus individual stars near this centre are invisible to us, and we see less than a half of the whole system of stars. For the same reason, we cannot see external objects which lie in or near the galactic plane; there is too much obscuring matter between them and us for their light to get through.

If the fog were much denser than it actually is, we should see only the stars in our immediate proximity, and a few of exceptional brightness beyond. If we were unaware of the fog, we should conclude that there is an excessive concentration of stars in our immediate proximity. Astronomers made exactly this mistake for a time, thinking that we lived in the midst of a 'local cluster' of exceptionally bright stars. Now that we know of the fog, we can allow for its effects and, for any assumed density of fog, can calculate the arrangement of stars which will exactly fit the observations. If we under-estimate the fog, we shall obtain a 'local cluster'; while if we over-estimate the fog, we shall get the opposite result, namely, that stars are exceptionally few in our neighbourhood, so that we are living in a 'hole'. Actually both results have been obtained in recent years by different investigators, but the simplest interpretation of their results is, I think, that they have respectively under-estimated and over-estimated the density of fog. There are rather strong reasons for thinking that there can be neither a 'local cluster' nor a 'local hole'—these are, in brief, that the whole galactic system is rotating with different speeds in different parts, so that both clusters and holes would soon be smoothed out. Thus the most likely value for the coefficient of absorption by the fog would seem to be that which just gets rid of the 'local cluster' without replacing it by a 'local hole', and this is about equal to the value mentioned above.

For a long time it was something of a puzzle to understand why a disk-shaped group of stars such as our galaxy should not all fall together at its centre of gravity, and it has often been suggested that our galaxy must be in rotation, as many of the external galaxies are known to be. In 1913 Poincaré calculated that our galaxy could be saved from this fate if it rotated about once every 500 million years. In the same year, Charlier found that the invariable plane of the solar system appeared to be moving against the background of the stars. Now the solar system keeps its invariable plane always fixed in the same direction, just as a spinning gyrostat does, so that, as Eddington immediately pointed out, the apparent motion found by Charlier could only mean that the background of stars was not at rest but was itself in

* Abstract of a Royal Institution discourse delivered on April 28.

motion. Such a movement of the background is now one of the well-established facts of astronomy.

A superficial study of the nearer stars suggests that they are moving at random, with differing speeds and in different directions. But a careful statistical investigation reveals law and order in the motions, not of individual stars but of statistical groups. The motion is best described by the statement that each group of stars (sufficient in number to justify statistical treatment, but also comprised within a sufficiently small volume of space) is describing an orbit about a centre. This centre is the same for all groups, and coincides exactly with the centre of the galaxy, as determined by Shapley from the arrangement of the globular clusters. Those groups which are farthest from the centre move most slowly, just as, in the solar system, those planets which are farthest from the sun move most slowly. The reason is, of course, that each star describes an orbit under the gravitational force of the rest of the stars, just as each planet describes an orbit under the gravitational force of the rest of the solar system.

Detailed statistical study of the stars near the sun shows that, on the average, the orbital speed of a star falls off by 1 km. a second for every 200 light-years increase of distance from the centre of the galaxy. This single datum, which is quite well determined, shows that the sun must take about 250 million years to perform its journey round the centre of the galaxy. Thus it must have completed some ten or a dozen orbits since the earth was born. If the sun is at a distance of 40,000 light-years from the centre of the galaxy, then it must describe its orbit at a speed of about 300 km. a second, a conclusion which agrees well enough with independent estimates made by spectroscopic measurements of the speed of the sun relative to the external galaxies and remote globular clusters.

The various data which have just been mentioned provide the means for weighing the mass which keeps the sun in its orbit, and so the galaxy as a whole. Estimates vary from 110,000 million to 180,000 million times the mass of the sun, so that it seems safe to say that the galaxy contains hundreds of thousands of millions of stars, although the majority are rendered invisible by the thick layer of fog which lies between them and us. It used to be thought that our galaxy was more massive than the others we see in the sky, but this no longer appears to be the case. We are familiar with groups of stars which are held together by their mutual gravitational attractions—the globular clusters provide an instance. There are also clusters of nebulæ which are held together in the same way. It is possible to determine the speeds of motion of the individual nebulæ of a cluster, and so deduce the gravitational forces needed to hold the cluster together. In this way, the average galaxy is found to have a mass of the order of from 100,000 million to 200,000 million suns. Thus there can be no doubt that the external galaxies are at least comparable with our own galaxy in mass.

Finally, it used to be thought that the external galaxies are substantially smaller than our own in size, but it has recently emerged that this too is fallacious. We only see a small part of a galaxy when we study its apparent size on a photographic plate; there is a much larger part beyond, which can only be detected by delicate photometric measurements. When we take this into account, the galaxies still show considerable differences in size, but the majority of the larger prove to be comparable with our own. On the whole, then, our galaxy is simply one of many similar galaxies. Probably about four million such can be seen photographically in the great Mt. Wilson telescope. If we allot 100,000 million stars to each, this makes a total of about $4 \times 10^{17}$ stars—a large number, although still small in comparison with the number of molecules in a cubic centimetre of ordinary air.

# REGIONAL PLANT ECOLOGY IN THE UNITED STATES

By DR. V. J. CHAPMAN
Botany School, Cambridge

THE last four years has seen the publication, by J. H. Davis, of three important papers on the vegetation of Southern Florida*. These three valuable papers yield a clear picture of the vegetation and its interrelations with soil types, climate and physiography. The area is especially interesting because climax vegetation is normally related to the climate, but Davis establishes a good case in this area for relating it primarily to the physiography. If the author continues these studies—as one sincerely hopes he will—the vegetation of Southern Florida will be known and understood in very considerable detail. This will be no mean feat for an area of such size. The majority of ecological studies usually refer to relatively restricted areas, and it is refreshing to find a study that embraces such a large region. A broad survey with accompanying detailed studies opens up major problems that would not be so evident in a study of a small area.

In the first paper, on the mangrove vegetation, Davis points out that they are primarily edaphic forests, a conclusion with which I agree, though I would add that there is also a physiographic element involved. Tropical forest of the 'hammock' type is regarded as the climax vegetation, though in the third paper it is also, albeit incorrectly, implied that mangroves represent a climax type. There is no evidence of a transition to brackish or freshwater marsh such as may be found in Jamaica. Davis studied the environmental factors in some detail and he shows that the mangrove species possess a wide tolerance of salinity and grow on at least four types of soil, one of which is a marine peat. I have arrived at similar conclusions from work in Jamaica. Davis relates the mangrove zonation to the height of the surface water, but here one feels that more evidence would be desirable. Some exceedingly interesting information is provided about dispersal. 10,000 Rhizophora seedlings are estimated to float towards the Tortugas every year; this represents only a proportion of the total crop because about 50 per cent of the seedlings from a tree remain embedded in the mud beneath it. The rate of survival at the end of one year is 50 per cent for Rhizophora, 30 per cent for Avicennia and 20 per cent for Laguncularia.

One of the important features of these three papers is the great use made of aerial photography in the study of the communities and the preparation of the

* Davis, J. H., "The Ecology and Geologic Rôles of Mangroves in Florida", Carn. Inst. Wash. Pub., 517 (1940); "The Ecology of the Vegetation and Topography of the Sand Keys of Florida", Carn. Inst. Wash. Pub. 524 (1942); The Natural Features of Southern Florida", State of Florida Dept. of Conservation, Bull. 25 (1943).

vegetation maps. At the present time vast quantities of air photographs of Europe, Africa and elsewhere must be accumulating, and it is to be hoped that they will become available to ecologists, who will then be in a position to study vegetation on a scale comparable to that of Davis.

The second paper, on the sand keys of Florida, is of particular interest because it adds a new set of vegetation maps to the series started by Millspaugh in 1907 and continued by Bowman in 1917. Changes in the vegetation of these keys over a period of thirty-seven years can therefore be studied. The Marquesas, like Jamaica, have few or no living corals, whereas living corals abound in the Tortugas. This is a peculiar feature of the Caribbean and one which greatly needs investigation. Davis concludes that marine currents are the main agents in the formation of these keys; but it is clear also that hurricanes have had a profound influence in the past upon their structure and also their vegetation. Two types of vegetation are recognized, the sea-strand and the mangrove swamp. The use of habitat is employed in the ecological nomenclature. This has been discouraged by most ecologists working in temperate climates, but tropical vegetation, and especially that of maritime regions, appears to have problems of its own. It may eventually prove desirable in such cases to employ a habitat nomenclature. I encountered a similar difficulty in Jamaica. The number of species recorded by Davis is not large; but this is typical of small islands of this type. The climates of the island groups vary sufficiently for the biological life-form spectra to show significant differences. The Schimperian view of 'physiological dryness' is adopted for the mangrove habitat; but the evidence available to-day scarcely supports such an interpretation.

The third paper covers the whole of Southern Florida, and all the various features are considered with a view to future regional utilization and planning. Aeroplanes, cars, special tractors and 'airboats' enabled the author to visit many areas that were previously almost inaccessible. Much of the region is, of course, covered by the famous Everglades. 'Glades' are grasslands flanked by forests, the 'ever' being added to signify that they remain green throughout the year. Much of the Everglades is dominated by the saw-grass, *Mariscus jamaicensis*, but there are also prairies, sloughs and 'hammocks'. These swamps originated as a result of regular seasonal flooding. The 'dismal' swamps with pine and cypress do not form part of the glades. The whole area can be regarded as a huge alkaline peat-bog, in many ways comparable to what the British Fens must have looked like in the past. Vast deposits of peat are here being formed under subtropical conditions. Unfortunately the natural water conditions have been upset and this is bringing about changes in the organic soils and the vegetation. The area is becoming drier and saw-grass is being replaced by bushes (= carr stage of Wicken Fen). The annual transpiration and evaporation from the saw-grass area is often more than the annual rainfall, and hence the water relations are closely bound up with those of Lake Okeechobee. Less water now flows out from this lake than formerly, and this is the main factor responsible for the present changes. Piles of marine shells found inland indicate past ease of travel by innumerable waterways many of which have now silted up. There is evidently scope here for a combination of archæological and botanical research in a manner similar to that so successfully carried out by Godwin and his co-workers in Great Britain.

Ten physiographic regions are recognized for Southern Florida and at least three old shore lines. The sands left by these seas form the main shallow sand soils in which little or no profile has developed. Beneath the Everglades there is an impervious marl layer, and Davis believes that these swamps would never have arisen were it not for this marl layer which effectively impedes drainage. If this is true, then the Everglades are related neither to the present climate nor to existing physiography but to past geological changes. Although twenty soil types are recognized, peats and marls are the outstanding features of this region. The soils are generally shallow and they have been much reduced by fires, which form an important determining factor of the environment. A detailed correlation is made between the different vegetation communities, individual species and the soil types.

A study of the water relations showed that the ratio, time water-logged to time dry, is the most important factor. Because of the low relief a few inches change in elevation makes a profound difference in the drainage relations.

Nine main types of vegetation are recognized and fifteen types are represented on the vegetation map. There is a very high proportion of woody plants, and Davis concludes that at least one half of the area is economically unprofitable and best left in the wild state. The characteristic 'hammock' forests represent the climax vegetation in Southern Florida. These possess a great diversity of plants, many of the species being tropical. If the fire danger were controlled these forests would be larger, while even at present their arrangement provides an indication of the drainage relations. Davis also considers that the cypresses (Taxodium) will not invade an area where water is continually standing on the surface because the seedlings require atmospheric oxygen.

These three papers contain many more valuable observations, but sufficient has been said to indicate their scope and importance.

# BIOLOGY IN WAR-TIME CHINA*

By Dr. PEI-SUNG TANG

Director of the Tsing Hua University Physiological Laboratory

THIS article will be of the nature of a report on the movements of biological institutions during the War and the activities of biologists associated with those institutions. No attempt will be made to survey the entire field of biology in war-time China, or to evaluate the work at present being done by Chinese biologists.

During the decade immediately preceding the War, there were several centres of biological investigation in China from which came a steady output of research. There were, for example, the physiologists at the Peiping Union Medical College, gathered round Robert K. S. Lim†, who virtually founded the science of physiology in China; the biochemists, whom H. Wu brought together in the same College; the Fan

* Condensed version.

† The Romanized names of the biologists mentioned in this article are those used by the authors in their publications.

Memorial Institute of Biology, where H. H. Hu and C. Ping established their School of Systematic Biology; and the Biological Institutes of Academia Sinica and of the Peiping Academy. The extent to which the work of these Institutes has been affected by the War differs greatly in individual cases.

The group led by Robert Lim included such men as H. C. Chang, known for his work on acetylcholine, and T. P. Feng, a pupil of Prof. A. V. Hill, whose review of muscle-nerve physiology appeared in the *Ergebnisse der Physiologie* shortly before the outbreak of war. Around this group was built the Chinese Physiological Society, and to it goes the credit of publishing the *Chinese Journal of Physiology*, perhaps the Chinese journal best known abroad. When war broke out in 1937, Lim was away in Malaya; but he returned to China and offered his services to the Government. In the winter of 1937, shortly before the fall of Nanking, he had but a handful of helpers. From that small start his Medical Relief Corps grew in three years to a sizeable army numbering thousands. This body rendered invaluable service to the fighting troops, not only in China but also in the Burma campaign, for which services Lim was decorated, by both the British and the United States Governments.

Lim is still with the Chinese Expeditionary Forces, serving in the capacity of medical supervisor, but he has now the added responsibility of establishing an Institute of Experimental Medicine for Academia Sinica. Of his former colleagues in Peiping, T. P. Feng has just arrived in Chungking and is temporarily attached to the Shanghai Medical College.

To the best of my knowledge, of the biochemists in H. Wu's department only C. Y. Chang, who is now attached to the Chung Cheng Medical College in Kiangsi, has as yet reached Free China. He was called to that College by Iping Chao, formerly of Tsing Hua University. With them is T. H. Chang, a nerve physiologist, formerly with the Biological Institute of the Science Society of China.

Of the original staff of the Fan Memorial Institute of Biology in Peiping, only its director, H. H. Hu, has reached the interior; this was shortly before the attack on Pearl Harbour. The work of the Institute is now carried out in part by the members of the Yunnan Institute of Economic Botany, established in the early part of the War as a result of Hu's far-sightedness. The Institute continues the survey work started by the Fan Memorial Institute some years ago, paying particular attention to the economic possibilities of plants endemic in the south-western provinces. Also located in Yunnan is the former Botanic Garden of Lushan, directed by the fern specialist, J. C. Ching. Part of the Fan Memorial Institute has moved to Chung Cheng University, in Kiangsi, of which Hu was president for several years.

Shortly after the fall of Nanking, the Biological Institute of the Science Society of China moved from Shanghai to the interior. The director, T. H. Chien, a veteran botanist held in affection by all, suffered great hardship on the long journey from the coast to the interior; but, undaunted, succeeded in moving practically all the equipment and a library of that Institute to a town not far from Chungking, where with a group of faithful colleagues he continues his work on systematic botany. Situated in the same town is the Institute of Zoology and Botany of Academia Sinica, which moved to the interior with its personnel and equipment almost intact during the early years of the War. H. W. Wu, C. C. Wang, C. C. Jao, Sicien Chen, C. C. Teng and others are carrying out research work on freshwater biology, entomology, parasitology, mycology and plant pathology.

Formerly there were four Institutes of Biological Studies in the Peiping Academy, namely the Zoological, Botanical, Physiological and Pharmacological Institutes. Of these the first three moved to Yunnan at the beginning of the War, and the last was left in Shanghai. On the death of Ting-heng Lou, the Zoological Institute was combined with the Physiological Institute, under the direction of Li-ping King. King himself is working on the pharmacology of Chinese herb medicine, while Tchang-si of the same department is conducting extensive surveys of the fishes of Yunnan from the point of view of their economic possibilities. Liou Tchenngo of the Botanical Institute has been making botanical surveys in the south-western parts of China. The director of the Pharmacological Institute, Tzan-Quo Chou, is still in Shanghai.

Also in Shanghai are two other well-known biologists who when last heard of were still engaged on their peace-time researches. One of these is C. Ping, the veteran zoologist who remained behind after the Biological Institute of the Science Society moved to the interior. The other is Tshou-su, who was provided with working facilities in his Institut de Biologie de Shanghai by the British Fund Committee.

C. Tsai has been the moving spirit behind the Medical School of the National Central University, which was transferred to Chengtu shortly after the War began. He has gathered around him a group of young men, including F. Y. Hsu and J. P. Chu, who are working mainly on the anti-hæmolytic action of lecithin and cholesterol. Tsai is now in the United States as one of six university professors invited by the State Department. With Tsai for a time were T. C. Tung and Mrs. Tung, who have now joined the national Tung Chi University in Szechuan and have been able to keep up their work on experimental embryology.

The National University of Chekiang moved to the interior shortly after the War began, first to Kiangsi, then to Kwangsi, and finally to Kweichow. Under the leadership of Sitsan Pai there has arisen one of the most active centres of biological research in war-time China. Apart from Pai, who published two articles on cytogenetics in the first issue of *Science Record*, the department has on its staff C. C. Tan, the geneticist, and T. L. Loo. Burg Tsai, formerly attached to the same department, is now director of the newly established Chinese Institute of Sericulture in the same province. This Institute was opened three years ago and is supported by the British Fund Committee.

The Institute of Psychology of Academia Sinica was moved to Kweilin during the first years of the War. It is situated in a picturesque town not far from the provincial capital, along with the Institutes of Physics and Geology of Academia Sinica. G. H. Wong, the director of the Institute, is continuing his work on physiological psychology, with tadpoles as experimental material. From the city of Kweilin comes news that Amos Kwangchin Penn has discovered in Kwangsi several species of plants which give fairly good yields of rubber and is exploring their industrial possibilities. Penn was formerly connected with the National Tsing Hua University, but

joined the National Kwangsi University after the fall of Hong Kong.

The work of the Physiological Laboratory of the National Wuhan University is in charge of Zangying Gaw, who works on cellular physiology, especially on the growth and metabolism of nitrogen-fixing bacteria. His work is partly supported by the Rockefeller Foundation.

At the National Southwest Associated University are to be found under one roof the National Tsing Hua University, the National University of Peking and the National Nankai University. Here four groups of biologists are engaged in research. In the Department of Biology of the University proper, Sesan Chen, the ecologist, works on the behaviour of ants. In the same Department, under the leadership of C. Y. Chang, head of the Department of Biology of the National University of Peking, a group of young men are working on physiological aspects of plant morphology. Mrs. Chang (*née* C. L. Tsui) is head of the Department of Biology at the nearby National Yunnan University, and continues her embryological studies with a group of young colleagues.

In the same University are the three divisions of the Tsing Hua University Institute of Agricultural Research. The Entomological Division is in charge of C. L. Liu. With him is C. J. Lu, formerly attached to the group of entomologists at Soochow University. Liu is particularly interested in the biological control of insect pests. A wealth of information on this subject has been accumulated and now awaits publication.

The second division of the Tsing Hua University Institute of Agriculture Research is the Division of Plant Pathology headed by the veteran mycologist F. L. Tai. With the able assistance of T. F. Yu, they are accumulating information on the fungi of Yunnan and on the breeding of disease-resistant varieties of crop plants.

My own department, the Physiological Laboratory of Tsing Hua University, is the third division of the Agricultural Institute. It was established in 1938 after the University had moved to Yunnan. It has been my good fortune to invite to my laboratory such able men as H. C. Ying, C. H. Lou, T. Shen and S. C. Pan. Although Ying is now officially on the staff of Peking University, Pan on the staff of the Department of Engineering and Shen in the Department of Biology, common interests and the convenience of sharing our limited resources have kept us together ever since their arrival at the laboratory. The Tsing Hua University Physiological Laboratory is dedicated to research in the broad field of general physiology, attacking certain fundamental physiological processes with the aid of physical and chemical procedures. Ying is engaged in plant hormone research and biochemical aspects of plant physiology. Lou is studying action potentials in plants and is interested in the problems of electro-physiology in general. Pan has been concerned with the industrial applications of micro-organisms, especially with the problem of alcoholic, acetic and lactic fermentations, while Shen's main interest is in the field of nutrition. My own work on cellular respiration still continues. For their work on the physiology of the silk-worm, several members of the laboratory were awarded the Ting Prize of Academia Sinica last year.

Interest in nutrition research is at present sweeping the country like wildfire, and a large number of biologists and biochemists are now engaged on work in this field. The reason for their enthusiasm is twofold. In the first place, existing conditions in the country necessitate the most economical management of our food resources; secondly, nutritional data are much needed for planning agricultural production in the general scheme of post-war reconstruction. Early in 1941 the National Bureau of Public Health called a conference on nutrition in Chungking which has resulted in the mapping out of a comprehensive programme of co-ordinated research in nutrition and food planning for the nation, to be carried out in collaboration with existing centres of investigation. Another result of the conference has been the formation of the Chinese Society of Nutrition, an organization devoted to the advancement of nutrition research in China.

Among the various institutions in which nutrition research is being carried out at the present time may be mentioned the Central University Medical College Department of Biochemistry, where Libin T. Cheng and his colleagues are determining the nutritive values of Chinese foods. At the National Szechuan University C. Y. Chen is doing similar work on certain food products commonly found on the market, such as soya bean flour and preserved eggs. Chen's work is published in his own journal, the *Nutrition Bulletin*, which came into being while he was at the National Peiping Agricultural College. At that time T. Y. Lo was his associate, but at present Lo is conducting a laboratory of his own at the National Chekiang University.

An Army Nutrition Institute has recently been set up at the Army Medical College in Kweichow, with H. Wan as director. The work of the Institute, as its title indicates, is chiefly concerned with nutrition problems in the Chinese Army. A number of publications have already come from that Institute in the form of bulletins and pamphlets, mainly for the benefit of army officers. At about the same time a nutrition laboratory was set up by the National Bureau of Public Health under C. F. Wang. The Institute is chiefly interested in Chinese diets and children's nutrition. As mentioned above, an important part of the work on nutrition at the Tsing Hua University Physiological Laboratory is directed by T. Shen, who has made extensive surveys on nutrition conditions in the Chinese Army and the diets of college students.

An outstanding event in war-time biology in China has been the arrival of Dr. Joseph Needham, of the Cambridge Biochemical Laboratory. Through his extensive visits to many of the centres of biological research he has brought new information and fresh ideas to Chinese workers. He has also helped materially in obtaining chemicals and apparatus, as well as microfilmed literature, through the British Council's Cultural Scientific Office in Chungking. To Dr. Needham and to Dr. John K. Fairbank, of the Office of the Cultural Attaché of the United States Embassy, biological workers in China are indebted for generous assistance.

Almost all the biological journals which were in circulation before the War have temporarily suspended publication because of insufficient facilities and economic pressure. The exceptions are *Sinensia* and the *Chinese Journal of Experimental Biology*, which are making a heroic struggle to appear, albeit irregularly. This accounts for the failure of other journals to reach our friends and libraries abroad. In place of these suspended journals, certain publications in foreign languages (mostly in English) have been brought out as a temporary measure.

These include the *Science Record* of Academia Sinica, which has a section on biology. In addition, there are the *Proceedings* of the Chengtu Branch of the Chinese Physiological Society and the *Biochemical Bulletin* of the Tsing Hua University Physiological Laboratory.

The impression created by this article will perhaps be that practical aspects of biological research predominate in present-day China. This is true to a large extent; but there are still a number of centres where a major part of the work is on academic aspects of biology. This is especially true of the Institute of Psychology of Academia Sinica, and to a certain extent of the Tsing Hua University Physiological Laboratory. The trend towards research of practical value is in fact unavoidable. In the first place the need of the country at the present is certainly on the practical side, and in the second place it is extremely difficult to carry out academic research of real importance under present conditions. Added to these reasons is the desire of every biologist to make himself useful to the country in its war effort. It is therefore not surprising to find biochemists, for example, putting their energy into such problems as army nutrition, the industrial possibilities of certain rubber-producing plants, vegetable oils and fermentation; while most of the systematic biologists have either turned their attention to agricultural problems or undertaken biological surveys of hitherto unexplored country.

# OBITUARIES

## Mr. Emil Hatschek

EMIL HATSCHEK, who died in London on June 4, at the age of seventy-five, carried out pioneer work in many branches of colloid science and did much to direct attention in England to this subject. In spite of the stimulus supplied by the classical researches of Thomas Graham, little was being done in this country on colloids when, in 1911, Hatschek started a systematic course of lectures on colloidal chemistry at the Sir John Cass Institute. This was, I believe, the first regular course on the subject to be given in England, and it continued until 1935, when Hatschek reached the age limit for retirement. From about 1910 until 1932 Hatschek was producing original papers, all marked by elegance and strong individuality, which appeared in various periodicals, including the *Proceedings of the Royal Society*, the *Transactions of the Faraday Society*, *Chemistry and Industry*, the *Biochemical Journal* and the *Transactions of the Institute of Mining and Metallurgy*, apart from the twenty-six or so that appeared in the *Kolloid-Zeitschrift*. These names do something to indicate the width of interest of his work. His services to colloid science were acknowledged when he was made the guest of honour at the Colloid Symposium at Ottawa in 1932, a distinction much appreciated by him. His contribution at Ottawa was a paper on "The Study of Gels by Physical Methods", a subject to which he had devoted much attention.

Hatschek was a Hungarian by birth, but his family migrated to Vienna when he was a child, and it was in that city that he studied at the famous Polytechnicum. Engineering, however, was his subject in those days, and it was as an engineer that he came to England in 1888, at the age of twenty. He became a naturalized British subject in 1900. He concerned himself professionally with matters of chemical engineering, especially filtration, in both England and America: problems that he met in this work first directed his attention to colloid science. About 1910 he retired from active professional work, although he still acted as consultant to certain undertakings, and, possessing private means, devoted most of his time to original experiment.

Hatschek's fancy took him into unusual fields, and in each he found matters of interest and importance. Two curious contributions of his were, one, on the changes in form of spherical segments of elastic gelatine, which on drying formed a gastrula reminiscent of the behaviour of living embryos, and, the other, on the growth of crystals in gels, which had a marked bearing on the growth of minerals. In particular, he showed that with gold the various forms that can be observed when crystals are formed in silica gel closely resemble the natural appearance of gold in quartz. His work on periodic precipitation bore on the banding observed in some natural minerals. He carried out many other elegant and unusual researches, but his greatest body of connected work was on various aspects of viscosity, especially on the anomalous viscosity of many classes of colloids. For this work his wide chemical knowledge, his clear-cut physical conceptions and his good general mathematical powers fitted him admirably. His co-axial cylinder viscometer for investigating the properties of colloidal solutions has been widely used.

In 1913 Hatschek published his "Introduction to the Physics and Chemistry of Colloids", which went into five editions. His "Laboratory Manual of Colloid Chemistry" also achieved wide popularity. In 1928 he produced his "Viscosity of Liquids", a standard work which was at once translated into German. He edited the "Foundations of Colloid Chemistry", a collection of classical papers, and wrote the articles on "Colloids" and "Viscosity" in the last edition of the "Encyclopaedia Britannica".

Hatschek was a man of very wide learning, with a fund of precise information on most matters. He had an excellent knowledge of botany, especially of field botany; he was well versed in the history and theory of music, and was a good pianist; in philology and general history he could hold his own in most companies; and he had a wide knowledge of the literature of England, France and Germany. He was a familiar figure at the Royal Institution and at the Faraday Society, in the government of which he played a prominent part for many years. In 1930 he became a member of the Savage Club, and was there almost daily to his death, acting in an oracular capacity. He never married and, in fact, all his attachments were intellectual rather than emotional. A powerful and original personality, his passing leaves a gap in British science.

E. N. DA C. ANDRADE.

## Dr. Burgess Barnett, M.B.E.

DR. BURGESS BARNETT, superintendent of the Rangoon Zoological Gardens since 1938, died on April 9 at Dooars, Bengal, at the age of fifty-six. He is perhaps best known for his work on the use of snake venom in the treatment of hæmorrhage and epilepsy, mainly carried out while holding the appointment of curator of reptiles of the Zoological Society of London during 1932–37.

He was the son of the late H. F. Barnett of Bescot

Hall, Walsall, and was educated at Marlborough College and St. Bartholomew's Hospital. After the completion of his medical training he took up practice in the Lobitos oilfields of Peru. When the War of 1914–18 broke out he returned to Great Britain and served as a captain R.A.M.C. in France and Macedonia. After the War he returned to Peru, where he continued his study of snakes and supplied many specimens to the London Zoological Society. His appointment as curator of reptiles enabled him to develop his main interest—the study of snake venom and its application in medical practice. His publications relate mostly to this subject, but he also wrote popular articles on natural history and chapters on herpetology.

In 1938 Barnett proceeded to Rangoon, where a new reptile house was being built, so that he could have the opportunity of establishing a snake farm for the collection of venom and making further studies on its medical applications.

During the present War he was awarded the M.B.E. for bravery in Burma, when, as principal medical officer of the Burma-China railway construction unit, he remained behind with refugees during the evacuation through the Chankan Pass, and gave them medical attention on a long march through uninhabited jungle country. E. HINDLE.

WE regret to announce the following deaths:

Mr. E. Bruce Ball, past-president and honorary life member of the Institution of Mechanical Engineers, and an honorary life member of the American Society of Mechanical Engineers, known for his work on hydraulic engineering, on June 17, aged seventy-one.

Prof. A. H. Reginald Buller, F.R.S., emeritus professor of botany in the University of Manitoba, on July 3, aged sixty-nine.

Prof. A. E. Conrady, formerly professor of optical design in the Imperial College of Science and Technology, on June 16, aged seventy-eight.

Dr. J. J. Lonsdale, organizing science master at the Sloane School, Chelsea, during 1914–33, an early worker on ionization by splashing, on June 12, aged seventy-one.

Sir Prafulla Chandra Rây, C.I.E., formerly senior professor of chemistry, University College of Science, Calcutta, on June 16, aged eighty-three.

Mr. George Steiger, formerly chief chemist of the U.S. Geological Survey, on April 18, aged seventy-four; and Dr. Roger C. Wells, who succeeded Mr. G. Steiger as chief chemist of the U.S. Geological Survey, on April 19, aged sixty-six.

# NEWS and VIEWS

## University of Reading: Chair of Agriculture

### Prof. R. Rae

PROF. ROBERT RAE, who has been professor of agriculture in the University of Reading for the past eleven years, has resigned from academic work on his appointment as agricultural attaché to the British Embassy at Washington. During his tenure of office at Reading, Prof. Rae has expended a large amount of time and energy on the expansion of the Department of Agriculture. This work has been highly appreciated by his colleagues and the many students with whom he has come in contact. The acquisition and development of the University Farm at Sonning-on-Thames was entirely due to his efforts. Before his appointment to Reading, Prof. Rae was professor of agriculture in Queen's University, Belfast, and previous to this he had teaching experience at the East Anglian Institute of Agriculture and the Hertfordshire Farm Institute. Many of his friends regret his departure from the sphere of agricultural education. Since the beginning of the War Prof. Rae has served on several agricultural committees connected with greater food production. More than a year ago he went on a lecture tour to the United States, which proved most successful, and where he is recognized as one of the leading authorities on British agriculture.

### Prof. H. G. Sanders

The University of Reading has appointed Dr. H. G. Sanders, fellow of St. John's College, Cambridge, as professor of agriculture, from October 1944. Dr. Sanders was educated at Wellingborough School until 1917 and, after serving for two years in the Army, proceeded to St. John's College, Cambridge, qualifying for the degree of B.A. in 1920. After a period of practical farm work, Dr. Sanders became an assistant in the Animal Husbandry Institute, Schoo of Agriculture, Cambridge. In the winter terms of the sessions 1926–29 he gave courses of lectures in the University of Reading on animal physiology. In 1932 he was appointed a University lecturer in agriculture at Cambridge. In 1940 he was appointed deputy executive officer of the Cambridgeshire War Agricultural Executive Committee, and in 1941 executive officer to the Hertfordshire War Agricultural Executive Committee. Dr. Sander's researches and publications cover a wide range of agricultural problems in both crop husbandry and animal husbandry. His best-known work is "An Outline of British Crop Husbandry", published in 1939.

## Royal Society of South Africa: Marloth Memorial Medal

THE Council of the Royal Society of South Africal has awarded the Marloth Memorial Medal to Dr. J. L. B. Smith, senior lecturer in chemistry in Rhodes University College, and D. Rivett, for a paper on "The Essential Oils of Agothosma". The Marloth Memorial Fund was initiated by the Cape Chemical and Technological Society, and is devoted to the perpetuation of the memory of Dr. Rudolph Marloth, the famous South African chemist and botanist. In 1939 it was handed over to the Royal Society of South Africa for administration. It is awarded in the form of a small payment towards publication of papers of outstanding merit in either chemistry or botany, and a printed medallion heads the paper. The Medal has never been awarded before, but the present paper is considered as of sufficient merit, both from the botanical and from the chemical points of view, to be the first for which this honour is conferred.

## Society for Freedom in Science

FOUR years ago, a circular letter was sent to a few scientific men suggesting the formation of a new society to promote the causes of pure science and of freedom in science. A group of thirty was thus formed, which became the nucleus of the Society for Freedom in Science. The Society has recently issued a statement of its purpose and aims, which are summed up in five propositions; put briefly, these are: (1) increase of knowledge by scientific research and its diffusion have a primary human value; (2) science can only flourish in an atmosphere of freedom; (3) scientific life should be autonomous; (4) conditions of research appointments should give workers freedom to choose their own problems; (5) scientific men in countries not under dictatorial rule should co-operate to maintain freedom of research.

The Society claims a present membership of 134, chiefly as the result of correspondence and the circulation of memoranda; but an effort is now being made to increase this number, so as to have firm backing for the Society's objects. It is feared that with the approaching period of reconstruction those who stress the applications of science to the detriment of so-called pure science and support the view that research should be centrally planned will be allowed undue influence, and the Society hopes to be in a position to insist on the claim for freedom in science. The Society is an informal body, with no rules, no regular subscription and no official president. Its affairs are conducted by a committee consisting of Dr. J. R. Baker, Prof. V. H. Blackman, Mr. R. Brown, Prof. J. A. Crowther, Prof. M. Polanyi, Dr. L. E. Sutton, Prof. A. G. Tansley and Prof. A. E. Trueman; the honorary secretary is Dr. J. R. Baker, University Museum, Oxford, from whom particulars can be obtained.

## Visual Education

MR. G. PATRICK MEREDITH of the Education Department, University College, Exeter, took up the investigation of the use of visual media in education in 1940, and his lectureship was converted in 1941 into a lectureship in visual education—a novel appointment. The work expanded. The accommodation and equipment provided enabled a centre to be established with a staff which now includes an assistant lecturer, Dr. Renée Marcousé. Their researches on the comparative values of different visual teaching techniques were described at a conference held at the centre during July 1–2. One of the most interesting features was the testimony of the teachers who took part in the research. Their enthusiasm for the new media was striking and the demand for new materials and methods was made clear. The following subjects were included in the discussions: the design of the experiment, the statistical techniques and interpretation of the results (including a new technique of analysis); classroom methods, the film and still pictures used, the children's responses; the functions of the museums, exhibitions and other resources; and lastly, the planning of educational film production. The speakers included Mr. G. Patrick Meredith, Dr. Renée Marcousé, Mr. Bernard Gillett, Mr. Edgar Anstey, Mr. Neilson Baxter and the teachers concerned in the research. Representatives of the museums, film industry and Board of Education were present. A detailed report is to be published in the autumn.

## Carnegie Corporation of New York: Annual Report

THE annual report of the Carnegie Corporation of New York, for the year ended September 30, 1943, includes the reports of the president, Mr. W. A. Jessup, and of the secretary and of the treasurer, and gives a complete list of grants voted during the year totalling 2,562,900 dollars. Income for the year was 4,114,952 dollars in the Main Endowment Fund applicable to the United States, and 355,288 dollars in the fund applicable to the British Dominions and Colonies, the interest on the funds being equivalent to 2·7 per cent on investment securities, as compared with a yield of 4·5 per cent in the period 1932–33. The president points out that by means of reserves for various purposes the Corporation has spread allocations for the payment of appropriation for certain long-time interests over a period of years and has built up a depreciation reserve as partial protection of the endowment and legacy. The fact that the income to-day is only three fifths of the income ten years ago has, however, modified the grant-making policy of the Corporation. The Trustees are faced with the necessity of reducing either the number of grants made or the amounts involved, and possibly both.

The president also refers to the growing practice among donors of naming the specific purposes for which money is to be used. A recent inquiry among some twenty institutions showed that less than 10 per cent of the current gifts were free to be administered or allocated by the board of trustees and executive officers of the institutions. The president points out that in many instances a better method would be for the giver to expect the recipient institution to be capable and informed enough, and ready to accept, a larger share of responsibility for determining the allocation of gifts to research, to improvement in teaching, for equipment and for other important purposes within its own organization. Foundations such as the Carnegie Corporation have an obligation to continue to use their freedom from local and regional prejudices and from the pressures to which even privately endowed educational institutions are suffering, to foster new ideas and to nurture the pioneer spirit in education. Speaking of experimental projects, he said that those responsible should not expect support to be continued long after the undertaking has passed the experimental stage. These views are based on a review of the record of academic and foundation experience in administering grants during the past thirty years. During the year 1942–43, 12,000 dollars were voted to the Institute of International Education for continued support of the American University Union in London; grants totalling 225,300 dollars were made to agencies and organizations concerned with international understanding including the Carnegie Endowment for International Peace, the Institute of Pacific Relations and the Ethnogeographic Board under the National Research Council.

## Gas Research Board: Annual Report

THE fourth annual report of the Council of the Gas Research Board has a special importance, covering as it does a period when the Board became associated with the Department of Scientific and Industrial Research. This, however, is only another step in a long course of development extending over nearly half a century, during which the gas industry

has maintained organized co-operative industrial research. Dr. J. G. King, formerly of the Fuel Research Station, has been appointed director, and Dr. F. J. Dent, who has been responsible for a large part of the research activity of the Joint Research Committee of the Gas Research Board and the University of Leeds, has been appointed joint assistant director.

Of the items mentioned, gas technologists will note with interest the progress in the work on the complete gasification of coal. This shows that several lines of work are being followed—direct hydrogenation under pressure, gasification in oxygen and steam under pressure, and catalytic synthesis of hydrocarbons from carbon monoxide and hydrogen. The laboratory work on these themes is in course of transference to large-scale working in plant erected in a provincial gas works. Research on gas purification holds promise of reducing the sulphur content of purified coal gas to one tenth of the figures currently obtained in public supply in Great Britain. Drying by infra-red radiation emitted by gas-heated sources is being studied and apparently offers certain advantages. Methane, a gas of high calorific value, is a principal constituent of coal gas, from which it can be separated by liquefaction to give a portable liquid fuel which in future may be of great service. Gas engineers have always taken great interest in refractory materials, and the present report again reveals this interest. The report may be said to show that the research association under its new style shows already a wide and widening range of activities.

## Terms Used in Telecommunication

THE modern rapid growth of the applications of radio and telecommunications technique makes it desirable, even in war-time, to keep as up to date as possible a collection of definitions of the various terms and phrases used by workers and students in this field. To give effect to this point of view, the British Standards Institution has just issued a revised and enlarged edition of B.S. 204 entitled "Glossary of Terms used in Telecommunication" (obtainable from the British Standards Institution, 28 Victoria Street, London, S.W.1, 2*s*.). This publication has been prepared in collaboration with the General Post Office and other organizations concerned with communications technique and practice. It comprises revised sections of earlier glossaries dealing with telegraphy, telephony, radiocommunication, television and radio direction-finding, together with a new section on fire alarms. An appendix collects together the various symbols used for the quantities defined in the glossary. While it is doubtful if all workers in this field will agree with all the definitions, the revision, collection and rearrangement of the terms in this new publication will be found of considerable use as a reference manual by all those concerned with the preparation of technical documents and publications, as well as by the large number of other scientific and technical workers in this rapidly expanding field of telecommunications.

## Radio-Telegraph Signals

A PAPER on high-speed recording of radio-telegraph signals was read recently in London before the Institution of Electrical Engineers by Messrs. R. B. Armstrong and J. A. Smale, in which the authors first describe the systems in most general use, and then give a brief definition of modulation requirements for telegraph services. The various sources of distortion encountered are fading, noise and interference from other stations, but chiefly phase distortion due to propagation over more than one route between transmitter and receiver. The on-and-off character of Morse signalling enhances the difficulties which come from most sources of distortion. The paper then describes the general characteristics required in radio receivers designed for the purposes under discussion, including a description of two types of receiver in current use. This is followed by a consideration of special requirements of the recording units into which the receivers work, with a description of a typical unit. The special measures provided to offset the three types of distortion previously mentioned are also dealt with.

Diversity reception is discussed, with particular reference to the special problems of combining the automatic gain-control systems and the receiver outputs. Recording by undulator is chiefly considered in the paper as a whole; but the discussion on the effects of distortion, and the counter-measures taken, is even more applicable to machine-printing systems, since the latter have less margins of tolerance in operation. The paper concludes with an indication of the trend of development towards different methods of signalling, which may reduce difficulties of reception and recording in comparison with the old on-and-off methods of conveying intelligence.

## Lighting Reconstruction

THE Illuminating Engineering Society has just issued the first three of a series of Lighting Reconstruction Pamphlets which are planned to be of service to Government departments, local authorities, borough engineers, architects and others who are preparing now for the lighting problems which will confront Great Britain during the period of post-war reconstruction. The present pamphlets relate respectively to "Principles of Good Lighting", "The Lighting of Public Buildings" and "The Lighting of Schools", and they provide excellent summaries of the broad principles of what is needed to make lighting efficient according to the particular application. The pamphlets are obtainable from the Society at 32 Victoria Street, S.W.1, at the uniform price of 1*s*. each, 9*s*. per dozen, or £3 per 100.

## Distilled Water

THE development of the water-still has been slow, the normal type of apparatus being an externally heated metal boiler and a condenser. These are very inefficient, due to the fact that the number of calories required to heat the incoming cold water to boiling point is small compared with the heat required to convert the water into steam, and many kilowatts are required for an output of 20 gallons per hour. There is also the disadvantage of fur deposition from hard water, which can be diminished by taking only a fraction of the rated output.

A new type of still, called the "Strip-Action Still", is announced by Messrs. Townson and Mercer Ltd., 390 Sydenham Road, Croydon, which uses raw steam such as is available in a factory, and is made in units with a capacity of one gallon per hour. The initial design was in heat-resisting glass. The steam passes through an outer jacket which is air-cooled, and deposits dirt and high-boiling liquids with part of the condensed steam. The clean steam then passes down a multi-surface spiral condenser and comes out at the bottom as distilled water. By avoiding much contact with air, the water is of appreciably better

quality in regard to $pH$ value than ordinary distilled water. The inner condenser is water-cooled, and the flow is adjusted so that the distilled water issues nearly at the boiling point.

## Processing Quartz

THE production of a small thin quartz plate from a large crystal weighing several pounds involves a long succession of operations, including repeated cutting, surfacing and checking. Each step requires some form of grinding or lapping, and with the extremely high precisions required and material so hard as quartz, these processes are slow and exacting, although multiple processing reduces the net time per crystal considerably. Until crystals began to be used extensively in electrical work, the grinding of hard brittle substances was limited chiefly to jewels, and the techniques and materials employed were not very well suited to a large-scale processing of quartz. As a result, a considerable amount of research and development was carried out in the Bell Laboratories to discover the most satisfactory methods and to design the most useful machines. An article by W. L. Bond (*Bell Lab. Rec.*, 22, No. 8; April 1944) describes the various lapping and grinding processes employed.

## Accidental Poisoning in the United States

IN the United States, about 1,200 deaths occur each year from accidental poisoning. Analysis of the 355 cases occurring among policy-holders of the Metropolitan Life Insurance Company during 1940–43 (*Statist. Bull.*, 25, No. 2; 1944) reveals the following. More than a quarter of the victims were pre-school children, and among these the commonest poison was strychnine (20 cases), taken in the form of sugar-coated strychnine pills intended for adults, followed closely by oil of wintergreen (17 cases), taken by drinking the pleasant smelling liquid intended for external application. Among the adults the list was headed by overdose of sleeping drugs (72 cases); 49 took poison (commonest were lysol, sodium fluoride) in mistake for medicine; 41 drank methyl alcohol believing it to be a satisfactory substitute for ethyl, and 18 drank poison in mistake for an alcoholic beverage.

## Anti-plague Campaign in Chimborazo

ACCORDING to Dr. C. S. Vera, of Riobamba (*Bol. Of. San. Panamer.*, 22, 875; 1943), a successful anti-plague campaign was carried out in the province of Chimborazo, Ecuador, during August 1, 1942–July 21, 1943. The central office set up in Riobamba directed the activities of the groups organized in each section of the province. 'Cynogas' and flame-throwers were used in destroying rat nests, and a paste of arsenic and phosphorus was used in rat burrows. During the year 43,876 rats were trapped (*rattus* 13,730, *alexandrius* 10,322 and *musculus* 19,815), and almost complete extermination was accomplished in some areas. The spleens of 23,629 rats were examined, but only one (*rattus*) was positive. The incidence of plague in Chimborazo was as follows: 1939, 82 cases; 1940, 40 cases; 1941, 30 cases; 1942, 1 case, and in the first six months of 1943 nil.

## Swedish Town Population

ACCORDING to recent statistics in the *Anglo-Swedish Review* of April, the population of the Swedish capital rose during 1943 by more than 21,000, which is the largest annual increase ever recorded, to 636,000. Greater Stockholm including the suburban districts of the capital now has 800,000 inhabitants, or one eighth of Sweden's entire population. The same increasing tendency is registered for most Swedish towns, 111 out of the country's 123 towns showing rising population figures; Sweden's second town, Gothenburg, has 290,000 inhabitants and the third largest, Malmö, 163,000.

## Summer School in X-Ray Crystallography

A Summer School in X-ray crystallography applied to industrial problems is being held in the University of Cambridge in September along the lines of the school organized last year which proved to be very successful. It is being arranged again by the Departments of Physics and of Mineralogy and Petrology in co-operation with the Board of Extra-mural Studies. In the course, which has been modified as a result of the experience of last year, emphasis will be placed on the interpretation of practical work and on the application of different techniques to various problems. It is particularly designed for scientific workers and technicians who are using the methods of X-ray diffraction in industry and who have had no systematic training in the subject. The Summer School will extend from September 4 to September 16. In view of the present shortage of staff, apparatus and materials, it will be possible to accept only a limited number of people, and application to attend must be made before July 24. Further information can be obtained from the Secretary of the Board of Extra-mural Studies, Stuart House, Mill Lane, Cambridge.

## Announcements

MR. G. D. H. COLE, University reader in economics, Oxford, and director of the Nuffield College Social Reconstruction Survey, has been appointed Chichele professor of social and political theory at Oxford as from October 1.

THE honorary degree of LL.D. has been conferred by the University of St. Andrews on Sir Robert Robinson, Waynflete professor of chemistry in the University of Oxford.

THE honorary degree of LL.D. has been conferred by the University of Aberdeen on Prof. Alexander Findlay, professor of chemistry in the University during 1919–43; Prof. V. M. Goldschmidt, professor of mineralogy and geology, University of Oslo; Sir William Wright Smith, regius professor of botany in the University of Edinburgh.

The degree of D.Sc. has been conferred on Dr. G. A. Cowie, for a thesis on "Study of the Effects of Manures and Rainfall on Yields of Crops grown in Rotation"; J. S. Farquharson for a thesis on "(1) Haboobs and Instability in the Sudan, (2) The Diurnal Variation of Wind over Tropical Africa"; Dr. H. W. Kosterlitz, for a thesis on "Some Observations on the Conversion of Galactose to Glucose in Mammalian Liver and in Yeast". The degree of Ph.D. has been conferred on Charity Waymouth, for a thesis on "An Investigation of Various Substances of Biochemical Importance for Tissue Growth".

MESSRS. H. K. LEWIS AND CO., LTD., 136 Gower Street, London, W.C.1, have been appointed sole distributing agents for the reproductions of German technical books issued by Mr. J. W. Edwards and Edwards Brothers Inc., of Ann Arbor, Michigan. A catalogue of the titles is in preparation. A copy will be sent on request.

# LETTERS TO THE EDITORS

*The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.*

## Mechanism of Brittle Rupture

THE low strength of brittle materials has been ascribed by A. A. Griffith[1] to the presence of discontinuities which have the properties of small cracks in these materials. Since this theory was published, however, several investigations have established the fact that glass exhibits the phenomenon of delayed rupture to a marked degree, and this is not easily explicable by Griffith's theory alone. The most recent of these investigations, by F. W. Preston[2] in the United States, reports the variation in strength of glass when loads are applied for periods of $10^{-2}$ sec. up to $10^5$ sec., the breaking stress falling from 14·3 kgm./mm.$^2$ for $10^{-2}$ sec. duration of load to 4·47 kgm./mm.$^2$ for $10^5$ sec. duration.

As a result of investigations which will be published shortly, I have been led to the hypothesis that glass consists of an elastic matrix which contains small pockets of 'quasi-viscous' material. These pockets take the place of Griffith's 'flaws'; and when the glass is subjected to a stress the initial load carried by the viscous material is conveyed to the matrix as relaxation of the stress occurs in the viscous material. In this manner a stress concentration grows with time in the matrix surrounding a 'viscous pocket'. Finally, such a pocket would become the equivalent of a hole in the matrix when the viscous material carried no stress.

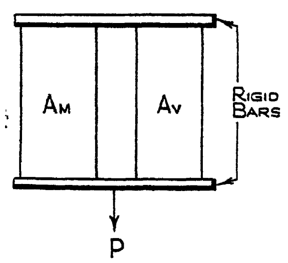

FIG. 1.

To represent the stress concentration occurring in the elastic material surrounding a viscous pocket, I have used the model illustrated in Fig. 1. This is intended to represent *local* conditions at a pocket, and it consists of two cylinders of the same height connected by rigid bars at each end. The area of cross-section of the elastic cylinder is $A_M$, and that of the cylinder of viscous material $A_V$. The sum of these areas is taken as 1, so that when a stress $P$ is applied to the system,

$$S_M A_M + S_V A_V = P,$$

where $S_M$ is the stress in the elastic matrix and $S_V$ the stress in the viscous material. This relation holds at any instant after the application of the load.

Now the *strain* in the two cylinders must always be the same (this means that the strain in the edge of the matrix surrounding a pocket is equal to the strain in the pocket material); and if we designate the strain at any instant as $\sigma$, then the stress in the elastic cylinder is $E\sigma$, where $E$ is Young's modulus.

If the viscous body had a true Newtonian viscosity, the stress-strain-time relationship for it would be

$$S_V t = \eta\sigma, \text{ or } S_V = \frac{\eta\sigma}{t},$$

where $\eta$ is the viscosity.

Hence, at all times,

$$E\sigma A_M + \frac{\eta\sigma}{t} A_V = P.$$

Now if the glass breaks when the strain in the elastic matrix reaches a constant value, say $B$, then the breaking stress, $P_B$, is related to the time of breakage by the expression

$$EBA_M + \frac{\eta B A_V}{t} = P_B,$$

which may be simplified to

$$P_B - a = \frac{b}{t},$$

where $a$ and $b$ are constants.

Hence if log $(P_B - a)$ is plotted against log $t$ a straight line should be obtained, and this has been done with F. W. Preston's results, as shown in Fig. 2. The value of $a$ was determined by plotting values of log $(P - 1)$, log $(P - 2)$, etc., against log $t$; the result being that log $(P - 3)$ yielded the line shown in Fig. 2.

It will be seen that the slope of the line is not unity; in fact $\frac{\delta \log (P_B - 3)}{\delta \log t} = 0{\cdot}126$, so that the equation for the line in Fig. 2 is

$$P_B - 3 = \frac{6{\cdot}3}{t^{0{\cdot}126}}.$$

This indicates that the model may represent the results quite closely if the pocket material is a 'quasi-viscous' substance of the type which G. W. Scott Blair[3] has investigated. Thus it is only necessary to represent the stress-strain-time relationship of the 'viscous' substance as $St^{0{\cdot}126} = \eta^*\sigma$, where $\eta^*$ is a constant. This corresponds with Scott Blair's expression

$$S^\beta t^\varkappa = \psi\sigma$$

in which $\beta = 1$ and $\varkappa = 0{\cdot}12$. These values of $\beta$ and $\varkappa$ would represent a substance of high 'viscosity' approaching the elastic condition, which is not entirely unexpected since the material with which we are dealing is a silicate.

It should be noted that the equation derived from the 'viscous pocket' theory represents the experimental results over a very long range of time, namely, $10^7 : 1$, which may be taken as a very good quantitative support to the theory. It is of special interest that the theory accounts for the difference between ductile and brittle materials as a difference in relations between the elastic and 'viscous' portions. A ductile body may be regarded as one which is constituted of a viscous material with inclusions of elastic pockets, whereas a brittle material is one which is predominantly an elastic substance containing inclusions of viscous pockets. In between these

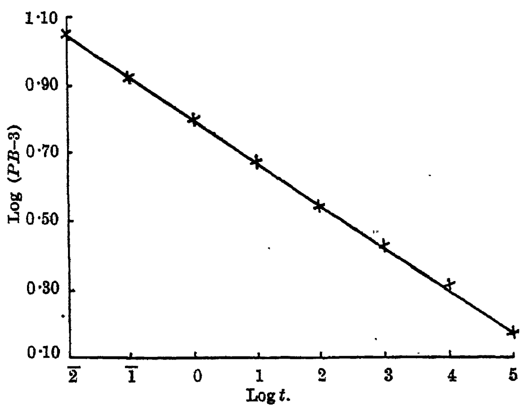

FIG. 2.

extremes there may be bodies which contain both these features to varying extents, and which may therefore be either 'brittle' or 'ductile' according to circumstances of the test.

## Place-Exchange Theory of Plastic Flow, as Applied to Polymers

THE place-exchange theory of plastic flow was originally developed by Becker[1], to account for the flow of metals. More recently a somewhat similar theory has been advanced by Eyring[2] to account for flow in polymeric materials. In the latter theory the flow process is regarded as the movement of a molecule, or segment of a molecule, from one position in the plastic to a neighbouring one, under the influence of thermal energy. If $E$ be the potential barrier separating two positions, and $f$ the stress, then the activation energy for the process is written as $E-bf$, where $b$ is a constant involving the dimensions of the 'unit of flow'. The rate of flow $\theta$ may then be written

$$\theta = \text{const.}\ e^{-(E-bf)/RT} \quad . \quad . \quad . \quad (1)$$

It can be shown from (1) that for very low stresses the system will show Newtonian behaviour, that is, for $bf << RT$, $\theta \propto f$, and Eyring has treated simple liquids along these lines[3]. For $bf > RT$ the following behaviour is predicted

$$\ln \theta = a + b'f \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

(The equations are given in their simplest form.)

We have recently completed an extensive series of measurements on a plasticized cellulose derivative over a stress range 2–160 kgm./cm.$^2$ and temperature range 16–100° C. The methods used were compression of cylinders and extension of rods, care being taken to analyse the total strain into its plastic (non-recoverable) and elastic components. In this note we are concerned solely with the plastic flow.

The important result of our work is that equation 2 is followed only at the lower stresses, that is, up to a certain stress value $f_0$ which is itself a function of temperature. In this range, $f < f_0$, we have further checked, in a qualitative way, the main assumption of the theory; thus we have found that the 'activation energy' for flow falls from *c.* 30 kcal. at 4·6 kgm. cm.$^{-2}$ to *c.* 11 kcal. at $f \geqslant f_0$. For values of the applied stress above $f_0$ we find that the activation energy is independent of stress. In fact, the flow may be described by the equation originally used by Bingham to describe the flow of solid–liquid dispersions through capillary tubes.

$$f \geqslant f_0, \quad \theta = A(f - f_0) \quad . \quad . \quad . \quad . \quad (3)$$

This equation could not have been predicted by the place-exchange theory as it stands. Its application gives hope for a simpler analysis of flow problems in industrial processes than could be achieved by equation 2. We should mention that similar results were obtained by Dillon and Johnston[4] for the extrusion of compounded rubber. Their work, however, by itself, is not directly comparable with ours owing to the presence of 'fillers' in many of their rubbers (that is, they are not dealing with a simple polymer system), and the possibility of 'plug-flow' at the lower stresses. In fact, it might be argued that their rubber-filler systems were analogous to the Bingham solid-liquid paste systems. However, our results would suggest that rubber without fillers may follow equation 3 at high stresses, and there are indications, in the paper quoted, that this may well be so.

It is of interest that we found no indication of a true yield-value, and we may hazard the opinion that in our system, whether or not a yield-value is observed is purely a question of duration of experiment and sensitivity of observation. In fact, it is possible to observe flow in our sensitive extension apparatus at stresses much below the apparent yield-value obtained in our compression plastometer. It is, of course, possible that if the plasticizer content were reduced, a true-yield value would appear. It is of interest that to a reasonable approximation, over a temperature interval of 40° C., the 'mobility constant' $A$ has the same temperature dependence as the intercept $f_0$, namely,

$$A = A_0\, e^{-11000/RT} \qquad f_0 = f_{00}\, e^{11000/RT}.$$

A further feature of our results was that at the very low stresses, in extension, the material showed strain-hardening, $\theta$ falling 20–30 fold over the initial 3–4 per cent extension, reaching an apparently steady value, very similar to the behaviour reported by Andrade for metal wires[5]. At the high stresses used in compression, we could not detect any such behaviour. Whether this was due to instrumental limitations we cannot at present say. It does, however, seem likely that any strain-hardened structure which may be formed initially cannot withstand the large shearing forces produced by the high stresses operative in the compression measurements.

It would seem that a critical attitude is required to the application of place-exchange theories in their present form, not only to the flow of plastics at high stresses, but also to the normal viscosity phenomena in liquids. Granting the application of the theory to plastics at relatively low stresses, it might be surmised that at the higher stresses the flowing molecules may pass over several energy barriers, and that the rate of flow is then determined by the rate of exchange of momentum, as visualized by Van der Waals' and Andrade's theories of liquid viscosity[6]. If this is so, it would argue for the possible application of the momentum exchange theory to the behaviour of simple liquids. It is hoped in the future to make experimental and theoretical investigations of this question.

Approval for publication has been granted by the Director-General of Scientific Research and Development, Ministry of Supply.

## Displacement of X-Ray Reflexions

A SMALL displacement of the X-ray diffraction maxima from the position determined by Bragg's equation $n\lambda = 2d\sin\theta$ may be caused by experimental conditions, such as the absorption of X-rays in the specimen, or it may be caused by imperfections in the crystal structure, as several authors have shown by theoretical considerations, starting from different assumptions[1,2,3]. It seems, however, that in the latter case no experimental evidence has been produced.

Some years ago, the indexing of the X-ray diffraction pattern of chrysotile caused considerable difficulties, which were ultimately solved by making allowances for a displacement of certain reflexions. In this case, of the thirty-four reflexions observed on the equator and on the second layer line, twenty-two were of the $\{00l\}$ and $\{20l\}$ type (crystal reflected copper $K\alpha$ radiation). These were comparatively sharp reflexions, and the agreement between calculation and measurements was so good as to exclude the possibility of any measurable displacement due to experimental conditions. Still, the remaining third could not be indexed, unless a variable axial length was used for the $b$-axis. Only then could the first layer line also be indexed. Such 'apparent' $b$ values, when plotted against the corresponding index $k$, lie on a smooth curve (Fig. 1), with a few exceptions. These exceptions are, apparently, the reflexions for which the indices $k$ and $l$ are both multiples of three, including zero. Furthermore, all these exceptional reflexions yield the same $b$ value. (More spots have been measured on photographs taken with molybdenum $K\alpha$ radiation, which give a similar picture to Fig. 1, though the measurements are less accurate.)

It is only putting the statement another way round to write that in the X-ray pattern of chrysotile some reflexions are displaced away from the central ordinate in a manner implicitly dependent on the crystal structure. The displacement may be between 0·15 mm. (for 110 reflexion) and 1 mm. (for 190 reflexion), in a camera of 60 mm. diameter, using copper $K\alpha$ radiation.

Quantitatively, the displacement has not yet been fully accounted for. The key to the solution lies in the fact that all the fuzzy spots, and only these, are displaced from the Bragg reflexion position. It is hoped to discuss this matter elsewhere in more detail.

Another interesting error of psychological origin was observed in this connexion. It was found that the distances from the central ordinate of the peaks of the reflexions 020, 110 and 130 on the microphotometer curves are 0·06, 0·05 and 0·11 mm.

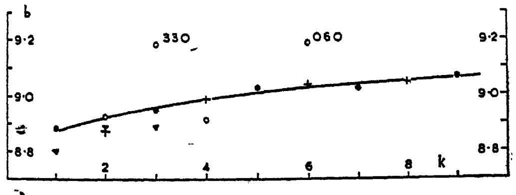

FIG. 1.

Fig. 1. 'APPARENT' LENGTH OF THE $b$-AXIS OF CHRYSOTILE PLOTTED AGAINST THE INDEX $k$. CAMERA 60 MM. IN DIAMETER, COPPER $K$ RADIATION.

O, reflexions $0k0$, on the equator; ●, $1k0$'s on the first layer line; +, $2k0$'s on the second layer line. ▼, microphotometer readings of the 110, 020 and 130 reflexions. Reflexion 040 is a very weak one.

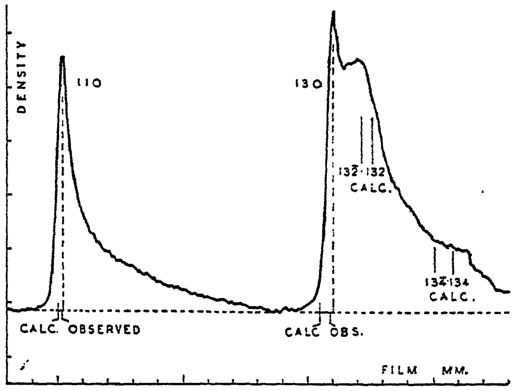

FIG. 2.

Fig. 2. MICROPHOTOMETER CURVE OF THE FIRST LAYER LINE OF CHRYSOTILE.
[$a = 5·32$, $b = 9·2$, and $c = 14·62$ kX., and $\beta = 93·2°$]. Crystal reflected copper $K\alpha$ radiation. The positions of the reflexions as calculated, and as measured by a travelling microscope are also indicated.

respectively larger than the same distances obtained with a travelling microscope. (A difference two or three times larger was obtained from photographs taken with a camera of 19 cm. in diameter for the 020 reflexion.) It seems that in the case of an unsymmetrical density distribution in reflexions such as those measured (Fig. 2), the eye tends to estimate the position of the middle of the line towards the steeper fall of the density. Such an error of judgment will be of importance when measuring unsymmetrical lines, such as partly overlapping reflexions, incompletely resolved $K\alpha$ doublets, or lines of considerable broadening.

## Age of the Saline Series in the Salt Range of the Punjab

WITH regard to recent letters on this subject[1], I would recall in addition that Mr. R. V. Anderson reported finding Quercus in the Punjab Saline Series[2]; while Foraminifera said to be from the same were referred by me to Ranikot species. Commenting on my report, Sir Lewis Fermor remarked that: "The discovery of these fossils indicates a Ranikot or post-Ranikot age for the Salt Marl Series, and appears to set at rest the long controversy about the age of the Salt Marl. We appear now to know that the age of this series is Tertiary and not Cambrian"[3].

Mr. Wadia and I had previously referred the Kohat salt to the Eocene[4]; and my later opinion is that all the salt of the region (Kohat and Punjab) is of basal Khirthar age. I have shown[5] that the Kohat-Potwar marine basin was isolated, at the close of Laki times, by a Waziristan ridge on the west, by the initial rise of the Salt Range axis on the south, and by the advance of the Himalayan axis on the north-east. The consequent desiccation of the basin produced Pinfold's 'passage beds' in its north-eastern parts, with salt to south and west;

and the succeeding Lower Chharat (early Khirthar) beds mark a fluviatile interlude before the extensive mid-Eocene transgression brought marine beds (Upper Chharats, Kohat Limestones, etc.) again over that region.

Thus the presence of Tertiary forms in the Punjab Salt Marl proves a Tertiary age for the associated salt, while the stratigraphy of the region more precisely indicates a basal Khirthar age for both the Punjab and the Kohat salt. Prof. Sahni's abundant confirmation of the first point goes far to clinch an increasingly strong case.

IN a letter dated February 10, one of us directed attention to the discovery of microscopic angiosperm, gymnosperm and insect remains in the Saline Series as exposed in the salt mines at Khewra and Warchha in the Punjab. The situations from which our samples were taken, in the body of a closely bedded series, placed it beyond doubt that the fossils were truly *in situ*; and their affinities make it obvious that the beds cannot possibly be as old as Cambrian.

These fossils were obtained by dissolving two kinds of samples: (*a*) lumps of rock-salt in which thin interbedded layers of saline earth ('kallar') were enclosed, and (*b*) portions of the 'kallar' bands alone, after scraping off the pure salt from both faces. We have now dissolved (*c*) lumps of the massive transparent rock-salt alone, taken from the same spots as before in the two mines. The Warchha salt has revealed shreds of carbonized pitted wood, and thick-walled tracheids with large circular separate bordered pits of the coniferous type. The Khewra salt has yielded, *inter alia*, felt-like masses of fibres of several different kinds; a fragment of wood with pitted cells; a cuticle recalling that of grasses, with a beautifully preserved stoma in an epidermis of elongated cells; and the chitinous coat of a small arthropod with paired jointed legs and traces of mouth parts.

Thus the rock-salt itself seems to be as rich in organic remains as the interbedded laminæ of saline earth. The indications are that the entire salt- and -'kallar' series in these mines is teeming with microfossils. For anyone now to claim that these fossils are 'derived' would be to claim that the whole series, even in the depths of these mines, has been churned up with extraneous matter. We cannot, of course, say whether the fossils reported by others were truly *in situ*. Ours certainly are; and although their exact age-value still needs to be critically assessed, there can obviously be no question of an age as ancient as Cambrian. On present evidence the only alternative seems to be that the Salt Marl is Tertiary.

## Preparation of a Stable and Active Pancreatin from Commercial Samples

THE problem of a pancreas protease preparation of a constant activity can be solved by the following preparative process:

1 gm. of the commercial sample of 'Pancreatin' (Parke, Davis and Co.) is mixed with 10 ml. distilled water and kept under toluene for about 24 hours at 37°. The mixture is then centrifuged, filtered and 50 ml. absolute alcohol are added. The centrifuged precipitate obtained may be washed with ether and is dried in a vacuum desiccator over sulphuric acid.

The yield of the dried substance is about 10 per cent of the original commercial product. It dissolves easily in water and is about five times as active as the original water extract (casein as substrate).

The preparation retains also the lipase (of weak activity) and the amylase of the mother substance.

While the water extracts or even the generally used glycerol extracts are not stable and their activity diminishes gradually on standing, even when kept under toluene (water extracts) in an ice box, the dry preparation seems to retain its original activity indefinitely.

## A Basic Principle Governing the Changes in Organisms under the Action of External Factors

THE present communication describes a general method of making a quantitative estimation of the response to external factors shown by biological systems of different order (individuals, taxonomic categories, populations or communities).

In studying the effect of training and learning, psychologists were the first to raise the question concerning the relationship of a change in the character to its original value[1]. In my recent work published in collaboration with my associate Dr. Gause[2] we gave three examples of "a negative relation between acquired and inherent characters of the organism".

My method consists in calculating the regression coefficients of positive or negative increments ($\Delta x$) of the character on their original values ($x$), both variables being expressed in the original units of measurement.

Four types of such a regression under the influence of an external factor can be established:

TABLE 1.

| Change in size of character | Relation of increase $\Delta x$ to character | Type |
|---|---|---|
| Increase | Positive correlation | I |
| | Negative ,, | II |
| Decrease | Negative ,, | III |
| | Positive ,, | IV |

The crossing of the $x$ axis by the regression line determines the point where $\Delta x$ is equal to 0. This

point is located at a distance $A$ from the origin of the co-ordinate system. $A$ represents the asymptotic value of our character or a lower or upper limit of its expression (see below). The coefficient of regression $b$ gives a measure of increments per unit of the character. It may be used in two ways: first, in ascertaining the efficiency of different factors acting upon a series of several groups of test animals, and secondly in comparing the response of different animal groups to the influence of the same factor, which shows the reactability of each particular group. Table 1 contains the constants $b$ and $A$ calculated for different examples taken from several branches of biology, medicine and agriculture. These constants were calculated from regression lines fitted by hand to observation points plotted on millimetre paper.

What is the mechanism of such types of biological reactions? The most plausible explanation seems to consist in the assumption that individuals or taxonomic groups used in experiments represent different stages of positive or negative growth. Thus, the most common type of exponential growth can be expressed by a function $x = A(1 - e^{-Ct})$. The differential equation of such a function, $\frac{dx}{dt} = CA - Cx$, clearly shows the velocity of growth to be inversely proportional to the size of the character $x$. The negative coefficient of regression in our type II is just an approximation of the function connecting the velocity with the size of the character obtained by using $\frac{\Delta x}{\Delta t}$ instead of $\frac{dx}{dt}$. Other types can be derived in the manner described from corresponding exponential growth-curves or curves of decay. In cases when growth of decay approaches an asymptote a kind of friction seems to take place. This friction is produced by components of the system which surround the character under question. Our types II and IV represent cases with an internal friction of components, while types I and III involve systems with a self-accelerating plus or minus growth.

TABLE 2.

| Name of the organism of the system | Character studied | Factor | $b$ | $A$ | Type |
|---|---|---|---|---|---|
| *Epilachna chrisomelina* (beetle)[3] | Diffuse black pigment between spots | Temperature | +1·5 | — | I |
| Children[4] | % hæmoglobin in blood | Honey diet during two weeks | −0·7 | 6·4 | II |
| Men affected by tertian malaria[5] | Spleen size (cm.) | Acrichine + chinoline therapy | +0·2 | 6·33 | IV |
| Black and white race and sexes[6] | Expectation of life at birth | Secular changes, 1901–20 | −0·13 | 54·4 | II |
| Man[7] | % correct answers obtained with the aid of tachistoscope | 3 days training | −1·0 | 87 | II |
| Patients[8] | Mitogenic radiation of blood | Hydrotherapy at a summer resort "Tzaltubo" | −0·54 | 32·5 | II |
| Populations of different countries[9] | Birth-rate per 100,000 | Secular changes, 1871–1913 | +0·40 | 170 | IV |
| Population of different States of U.S.A.[10] | Vital index | Secular changes, 1919–21 | +0·24 | 20 | I |
| Different soil types[11] | Oat yield (centners per hectare) | Fertilizer | −1·00 | 255 | II |

A general principle of a quantitative response of elements in biological systems (and very likely in physical also) to external factors may be expressed as follows:

($A$) Positive changes (increments) in a character are: (I) directly proportional to its original values, if the growth of the character is not limited by an upper asymptote; in such a system the component is exposed to a stimulatory action of adjacent components; and (II) inversely proportional to its original values if the character is limited by an upper asymptote; in such a system the component is exposed to the inhibitory action of adjacent components.

($B$) Negative changes (decrements) in character are: (III) inversely proportional to its original values, if its changes are not limited by a lower asymptote; in such a system the character is exposed to a stimulative action of other components; and (IV) directly proportional to its original values, if the character is limited by a lower asymptote; in such a system the character is exposed to an inhibitory action of adjacent components.

## Densities of the Embryonic Stages of Sea-Urchins

RECENTLY the densities of the early stages in the development of the very common sea-urchin, *Psammechinus miliaris* (Gmelin), have been obtained by the displacement method. The figures are as follows:

| | Temperature | Density |
|---|---|---|
| Ova | 9·8 °C. | 1·0725 |
| Zygotes (1 hr.) | 10·4 | 1·07360 |
| Blastula (embryos, 14 hr.) | 11·0 | 1·07582 |
| Blastula (larvæ, 20 hr.) | 9·8 | 1·0793 |
| Gastrula (late, 44 hr.) | 9·8 | 1·08390 |
| Echinopluteus (early, 68 hr.) | 9·8 | 1·09626 |

Both ova and zygotes were left in large dishes of sea-water for an hour. The densities of the ova and zygotes have been twice confirmed, and similar figures were obtained for the ova and zygotes of *Echinus esculentus* L.

In *P. miliaris* there is therefore a definite and gradual increase in density; but the figure which is

of outstanding importance is that for the zygote, which exceeds that of the ovum in spite of the inclusion of a large amount of liquid of a lower density.

Within an hour of fertilization taking place the zygote 'puts out' the very familiar fertilization membrane, which is separated from what was the original ovum by a clear space containing a colourless liquid. Measurement has shown that while the diameter of the original ovum is practically unchanged, the diameter of the whole zygote, including the membrane, is considerably increased, with the result that the volume of the zygote is more than twice that of the ovum. In the past, there has been a great diversity of opinion as to the nature both of the fertilization membrane and of the liquid enclosed. From simple basic reasoning we should expect the enclosed liquid to be slightly hypertonic to sea-water and to have a similar density. The density of the Plymouth sea-water at 11·0° C. was 1·02663, and the density of the enclosed liquid could therefore scarcely exceed 1·03. Hence, taking the density of the ovum as 1·07 and that of the surrounding liquid as 1·03, we should expect the density of the whole zygote to be 1·05, or very nearly so, instead of which it is 1·0736. When, therefore, the ova are left in sea-water, there is a very definite increase in density; and it would seem that this increase can only be attributed to a great intake of calcium ions, which on reaching the cell proper, immediately begin to separate out as cryptocrystalline granules of calcite. Calcium ions would not cause any appreciable increase in density, but calcite granules would, since their density is 2·7.

Much remains to be done, but unfortunately it is too late in the season to undertake it now. We know that spicules of calcite occur in the blastula larva stage. They are definitely crystalline, and in the first stages are intracellular and cannot have come into existence suddenly. This is clearly indicated, apart from anything else, by the gradual increase in density. The recrystallization of calcite from very finely divided granules of calcium carbonate is a well-known but none the less a complicated process even when it takes place in simple inorganic solutions. The protein in the echinoderm cell would probably act as a protective colloid and complicate matters considerably. It is known that calcium ions play a most important part in the early embryology of echinoderms, and also that the presence of excess of lithium ions prevents the normal development of echinoderms, especially in the earliest stages.

This is far too big a problem to discuss here, but the fact remains that while freshly precipitated calcium carbonate recrystallizes normally from sea-water, or from a solution of sodium chloride of the same strength, it does not crystallize normally from a solution in which the sodium is replaced by lithium.

The above concept of the great intake of calcium is strongly supported by the work of Ephrussi and Rapkine, as recorded by Needham[1], on the ash of the echinoderm egg. The figures are as follows:

| Hours after fertilization | | 0 | 12 | 40 (Pluteus) |
|---|---|---|---|---|
| Total ash, % dry weight | .. | 1·5 | 9·1 | 16·8 |
| Total ash, % wet weight | .. | 0·34 | 2·06 | 3·56 |

There are, of course, slight variations in the densities and also in the volumes of ova and zygotes, but in all cases investigated so far the density of the latter exceeds that of the former, which is the really important point.

In a previous communication[2], I recorded the fact that a ripe ovum in the oviduct of *Calanus finmarchicus* may increase its volume nearly twenty-two times within a few hours of extrusion. I also pointed out that in certain cases such volume changes took place irrespective of syngamy. Clearly in all these cases a consideration of *density* must preclude the assumption that these great changes in volume can be due to an intake of water alone.

## Composition of Coal

DETAILED research into the composition of coal demonstrates its intricacy. There can be no true understanding of this complicated and important substance if the results of research are confused by the use in varying senses of descriptive terms.

A recrudescence of confusion has recently arisen around the use of the word 'anthraxylon' as though it were synonymous with 'vitrain'. In their book "Geology in the Service of Man", Prof. W. G. Fearnsides and Dr. O. M. B. Bulman say (p. 108) "black, shining, bright coal ('vitrain' or 'anthraxylon') also composed of woody fragments". This is misleading: 'vitrain' and 'anthraxylon' are not equivalent, and 'vitrain' may or may not be composed of woody fragments.

I originally demonstrated and defined 'vitrain' in 1919[1]; in the following year Dr. Thiessen[2] described 'anthraxylon' as being layers which "correspond to the larger pieces of woody peat". Following my paper of 1935[3], an international agreement about coal terminology was achieved at the congress at Heerlen in the autumn of the same year[4].

It is particularly unfortunate at the present time when coal research is receiving wider recognition that confusion should be exacerbated, so that one must state emphatically that the term 'anthraxylon' cannot be used as the equivalent of 'vitrain'.

## Factors in the Production of Honey

I MUST apologize for having misquoted Miss Betts in my article in *Nature* of May 13. Her optimum figure for maximum sugar intake is 56 per cent, not 40, and incidentally is nearly independent of temperature. My conclusion is not affected. It is interesting to note that for a given concentration she established that the sugar intake is roughly doubled between 15° C. and 25° C. and follows roughly a linear law over a wider temperature range. The optimum concentration is nearly independent of temperature.

E. B. WEDMORE.

# HARDENING AND DARKENING OF THE INSECT CUTICLE

By R. DENNELL
Imperial College Field Station, Slough, Bucks

IT has long been known that the darkening of the insect cuticle which often follows ecdysis or metamorphosis is due to enzyme action. Tyrosinase has often been shown to be present in the body, and Bhagvat and Richter[1] have found in certain soft cuticles an active polyphenol oxidase. The chromogens involved, 'dopa' and related dihydroxyphenols, have been identified in a number of insects[2,3], and it has been suggested[4] that they play an active part in hardening the cuticle, by providing on oxidation ortho-quinones which 'tan' the protein constituents by the introduction of aromatic cross-linkages.

Considerable information on this subject is therefore available, but its integration into a coherent account is still largely incomplete. In particular, the functional connexion between the secretion of the pupation hormone and the changes in the cuticle is obscure. A recent morphological and histochemical study of the larval and pupal cuticles of *Sarcophaga falculata* (Dipt.) has, however, produced significant results.

The soft cuticle of the mature larva consists of an outermost very thin resistant epicuticle, covering a thicker ($4\mu$) layer of protein unassociated with chitin which may be termed the secondary epicuticle. Beneath these lies the endocuticle, a laminated chitin-protein complex of two distinct layers. The outer, laid down early in larval life, possesses pore-canals[5], but the inner, added later, when the chitinization of the cytoplasmic filaments of the canals is complete, has none.

The secondary epicuticle carries an oxidase, readily demonstrated by the 'Nadi' reagent, which is capable under experimental conditions of oxidizing catechol and 'dopa' rapidly, and tyrosine much more slowly. It is inhibited by cyanide, but not by sodium azide, and is resistant to drying and to treatment with alcohol, acetone, and chloroform. Moreover, at pupation the outer layer of the endocuticle gives a positive reaction to the ferric chloride test for orthodihydroxyphenols. Darkening of the cuticle begins at the epicuticle, where enzyme and substrate meet, and spreads inwards through the outer endocuticle, which is thereby converted into the hard and dark exocuticle of the puparium. The inner layer of the endocuticle does not darken, one reason for this being that it lacks the necessary phenol.

The accumulation of a dihydroxyphenol in the outer endocuticle coincides with the appearance in the blood of a similar phenol. That this phenol is not produced by tyrosinase activity after withdrawal of the blood for test is clearly shown by subjecting early pupæ to hydrogen cyanide vapour before opening, and withdrawing the blood into a small quantity of dilute hydrogen cyanide. Blood so obtained darkens on exposure, and gives faint but positive reactions to tests for dihydroxyphenols. The source of the phenol seems reasonably to be found in the oxidation *in situ* of the blood tyrosine by tyrosinase.

Larval blood, when tested at intervals with Millon's or Mörner's reagents, shows a progressive increase in its tyrosine content from the cessation of feeding to the onset of pupation, and thereafter shows a decline, and this is confirmed by the results given by a quantitative examination of the blood carried out by Dr. G. Fraenkel before this work was begun (private communication). It may be postulated that the decline in tyrosine content at pupation indicates its consumption as the blood phenol is produced and removed by oxidation in the cuticle.

Although tyrosinase is known to occur in insect blood, its source has not been shown. Drawn blood and dissected larvæ have therefore been examined after treatment with the 'Nadi' reagent, cytochrome oxidase having been inhibited by methyl alcohol. A positive reaction to this treatment, apart from that given more feebly by the secondary epicuticle, is given only by a small number of hæmocytes which closely resemble the œnocytoids described by Wigglesworth[6]. In addition to occurring free in the hæmolymph, they are found also in small clusters adhering to other tissues between the main posterior spiracular trunks. First noticeable in larvæ which are ceasing to feed, they increase in number as the crop is emptied, disappearing again shortly before pupation. On the addition of catechol to the blood, they rapidly darken; and in blood which is allowed to stand they darken more slowly. It seems clear that they are centres of tyrosinase synthesis. In freshly drawn blood the œnocytoids give a positive 'Nadi' reaction only after treatment with methyl alcohol—a feature which will be discussed later.

In late larval life, therefore, both tyrosine and tyrosinase are present in the blood, which darkens on exposure but not *in situ*. The reason for the inability of the blood to darken within the body seems due to the reducing properties of the hæmolymph. Kuwana[7] has distinguished clearly between a stable reducing fraction of the blood of silkworms, due to uric acid and glucose, and an unstable fraction, which increases greatly before ecdysis and pupation, falling sharply as these changes proceed. The unstable fraction decreases on exposure of the blood. In the present work the unstable fraction is provisionally regarded as being stabilized *in situ* by the action of an unidentified dehydrogenase, a view supported by the fact that the blood of late Sarcophaga larvæ will reduce tolylene blue almost completely, and phenol-indo-2 : 6-dibromophenol completely. Allowing the blood to stand, or treating it with methyl alcohol or chloroform, however, causes full return of colour to the dye solution. The same treatment greatly accelerates the darkening of exposed blood, due possibly to destruction of dehydrogenase and release of tyrosinase activity. In agreement with these observations, Graubard[8] obtained a higher effective tyrosinase yield from Drosophila larvæ after treatment with chloroform water.

Tyrosinase activity in the blood, prior to pupation, may therefore provisionally be regarded as being held in check by the reducing power of a dehydrogenase, tyrosine being reduced as rapidly as it is oxidized. This is further indicated by the inability of the œnocytoids to give an immediate 'Nadi' reaction without previous alcohol treatment, and by the darkening, first pointed out to me by Dr. G. Fraenkel, which is caused in intact larvæ by immersion for 24 hours or more in methyl alcohol. Larvæ which are ceasing to feed darken slightly at each end, and older larvæ and young pupæ blacken completely. On the other hand, young larvæ undergo no change, and isolated pieces of cuticle are not darkened under the same conditions. Similar results

are given, but more slowly, owing perhaps to slower penetration, by solutions of phenyl-urethane, phenyl-urea, and other narcotics known to inhibit dehydrogenases. Sections reveal that this induced darkening proceeds inwards from the epicuticle and closely simulates the natural process, although unaccompanied by normal hardening. Clearly a phenol, derived from the blood, is oxidized by the polyphenol oxidase of the epicuticle.

The significance of the increase in the unstable reducing fraction of the blood before pupation noted by Kuwana may therefore be explained by the simultaneous accumulation of tyrosine and tyrosinase, although the meaning of the increase before ecdysis, which is followed in the silkworm by cuticle growth but no darkening, is less clear. However, the speculation is inevitable that one effect of the liberation of a pupation hormone may be to modify the reducing properties of the blood by dehydrogenase inhibition, so leading to the release of tyrosinase activity, the production of a polyphenol, and the ultimate hardening and darkening of the cuticle.

A full account of this work, together with observations on the structure and growth of the cuticle, will be published in due course.

## CHARCOAL BRIQUETTES AS LOCOMOTIVE FUEL

By Dr. H. GREENE and T. N. JEWITT
Agricultural Research Institute, Anglo-Egyptian Sudan

A. F. JOSEPH and B. W. Whitfield[1] described in 1921 the production of charcoal briquettes made from Sudan woods. They used as binder gum arabic or sorghum flour, both of which are available locally. Such briquettes are satisfactory for firing a stationary boiler, but are quite unsuitable as locomotive fuel. For this use 20–25 per cent volatile matter is needed; furthermore, the briquettes have to withstand the severe conditions within the locomotive fire-box where, if the briquettes are weakly bound, forced draught and shaking may cause loss of fuel and where high temperature may produce clinker. On the instructions of Dr. J. D. Tothill, director of agriculture and forests, Sudan Government, work was resumed with the war-time object of finding a locally produced substitute for coal needed by the Sudan railways.

The previous workers had used a falling weight to compress their material. Lacking normal briquetting equipment we devised a hand-operated drop stamp mounted on wooden baulks. This drop stamp produces briquettes 7 in. × 6 in. × 3 in. at a rate exceeding one ton per working day, and enabled us to prepare the rather large amounts needed for full-scale locomotive fuel trials.

Pitch (Mexphalte *D.H.* 75/85) was incorporated with the charcoal (1 : 9 parts) and is considered essential. We had no means of steam-heating the mix as in normal briquetting practice, and therefore added gum arabic as primary binder. Ground charcoal and pitch, well mixed with water and gum solution, was stamped into briquettes by three impacts from a 75 lb. weight having 6 ft. fall. The freshly made briquettes can be handled with care and, in this hot climate, harden on drying to withstand crushing loads up to 2,000 lb. per sq. in. Strongest briquettes are obtained from a mixture containing about 60 parts water to 100 parts dry matter. Strength also depends upon a number of other factors, notably gum content, number of impacts, method of grinding, etc.

Charcoals available in the central Sudan are made from three kinds of acacia: *A. arabica* Wild., ash content 3–5 per cent; *A. seyal* Del., ash content 5–11 per cent; *A. mellifera* Benth., ash content 6–15 per cent; *A. arabica* Wild., which forms riverside forests within the 400–600 mm. rainfall belt, is of value as rough timber and also as fuel. *A. seyal* Del. is a prominent member of the thorn grassland association found on moderately alkaline clay soils receiving summer rainfall of about 600 mm. This acacia produces a marketable gum, but is otherwise useless, since when cut it is severely attacked by boring beetles (Sinoxylon spp., Bostrychidæ). The shrub-like *A. mellifera* Benth. is of use only as a source of charcoal. It is found in almost pure stands on clay soils receiving about 500 mm. summer rainfall. The charcoal used in Trials 3 and 8 (see below) was reputed to be mainly *A. seyal* Del., which is perhaps the most promising source. A consignment of *A. mellifera* Benth. charcoal was briquetted and burned in Trials 5, 6 and 7, the failure of which was due to causes not associated with the variety of charcoal used. The charcoal used in Trials 9, 10 and 11 was a well-mixed consignment believed to consist for the most part of *A. arabica* Wild. Reliable comparison of these three charcoals as constituents of locomotive fuel is not yet available, since other factors enter into the trial data. As another possible source of supply, some cotton-stalk charcoal was prepared, but owing to its high ash content (17 per cent) and low density was considered unsuitable as locomotive fuel.

It is extremely difficult to reproduce on a small scale conditions inside the fire-box of a locomotive steaming with full load. For this reason, the full-scale trial is the only valid test of a proposed coal substitute. Data obtained in such trials by inspectors of the Sudan Railways are tabulated below.

A locomotive with a 200-ton load steamed fairly well with charcoal-pitch briquettes made as described above, but it was seen that more volatile matter was needed. This was provided by dipping the air-dry briquettes in furnace fuel-oil. The mechanical strength of the briquettes is somewhat reduced by dipping in oil, but their resistance to rain is notably enhanced. In this way considerable quantities were made conforming fairly closely to the following percentage composition: charcoal, 75; pitch, 8; oil, 8; gum, 4; water (lost at 105° C.), 4. Of these constituents water is the most variable, since the charcoal absorbs 2–8 per cent water at relative humidities of 20–80 per cent. Oil content decreases with time, owing to slow volatilization.

Briquettes of this type were used in a number of full-scale fuel trials using Prairie type locomotives of 33·1 sq. ft. grate area. The accompanying table gives details of successful runs which were made with service trains running to schedule at the moderate speeds customary in the Sudan. Normal

steam pressures (170–175 lb. per sq. in.) were maintained except in Trial 11.

| Trial | Load (tons) | Run (km.) | Running time (hr. | min.) | Av. steam pressure (lb./sq. in.) | Fuel used (kgm.) | Equiv. evap. | Cal. value (B.T.U.) |
|---|---|---|---|---|---|---|---|---|
| 3 | 753 | 313 | 7 | 14 | 175 | 4970 | 8·06 | 12830 |
| 8 | 539 | 313 | 6 | 54 | 170 | 4920 | 7·33 | 12140 |
| 9 | 750 | 266 | 6 | 02 | 175 | 6037 | 6·17 | 13690 |
| 10 | 733 | 313 | 7 | 12 | 175 | 5611 | 6·88 | 13220 |
| 11 | 634 | 313 | 7 | 48 | 160 | 6580* | 7·23* | mixed fuel |

Representative figures for 'equiv. evap.' of coals under conditions of these trials are: Welsh or American coal, 9·4; South African, 8·7; Indian, 8·2.

In all these trials the charcoal was ground in edge-runner mills. For material used in Trials 3 and 8, the following is a specimen sieve analysis.

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Less than | | 8 | 16 | 30 | 60 | 100 | 200 | I.M.M. |
| Greater than | 8 | 16 | 30 | 60 | 100 | 200 | | I.M.M. |
| | 15 | 15 | 12 | 16 | 9 | 13 | 19 | per cent |

Coarser material (less than $\frac{5}{8}$ in.) was used in Trials 9 and 11, while that used in Trial 10 was intermediate (less than $\frac{1}{4}$ in.). The trial results fell off accordingly, Trial 9 being inferior to Trial 10, which is inferior to Trials 3 and 8. With these coarser materials it was observed that a larger proportion of fuel was carried away unburned and accumulated in the smoke-box. In Trial 11 we remedied this by burning the briquettes in 50/50 mixture with an American coal, but this and other similar trials were unsatisfactory for, although no data are available as to the performance of the American coal used in Trial 11, if the average figure of 9·4 for equiv. evap. is taken, it indicates that the briquettes were burned inefficiently. The failure of such trials is due to troublesome clinker formation caused, it is thought[2], by admixture of the siliceous ash of the coal with the basic ash of the charcoal. A similar formation of clinker occurs with charcoal-pitch briquettes to which 5 per cent of siliceous fine soil has been added.

Owing to the large demand for pitch for various war purposes, we tried to do without this constituent. The briquettes, however, disintegrated in use and gave poor results (equiv. evap. 5·08 and 4·62 in Trials 5 and 7). These failures occurred although the briquettes, which had been given a higher proportion of oil, resembled the successful ones in calorific value (12310 B.T.U.) and ash content (about 10 per cent). Considerable quantities of briquettes rejected owing to mechanical weakness, damage by rain, etc., were remade and satisfactorily disposed of in shunting engines or used to fire a stationary boiler, for which purpose they roughly equalled coal.

It became clear at an early stage of our work that the grinding of charcoal to a suitable powder was the most difficult part of the whole process. The product obtained from edge-runner mills is satisfactory, but much difficulty was experienced with charcoal pulverized in beater type mills which continually produced weak or badly cracked briquettes. Internal strains are gradually released when charcoal is moistened, and we have some reason to think that this difference in behaviour depends in part on the fact that charcoal was moistened before being fed to edge-runner mills but was fed dry to beater type mills. Neither sieve analysis nor microscopical examination of the fine particles revealed any notable feature other than the rather less rounded shape of particles obtained from a beater type mill.

One satisfactory full-scale trial was carried out using briquettes made from charcoal which was wetted and then crushed by an ordinary garden roller and stirred by rakes to prevent packing of the fragments into a resistant bed. In this trial the briquettes were burned in 50/50 mixture with American coal, some steam pressure being lost owing to formation of clinker. (Trial 12. Load 777 tons; run 313 km.; running time 9 hr. 34 min.; av. steam pressure 150 lb./sq. in.; fuel used 4,938 kgm.; equiv. evap. 8·26.) Since edge-runner mills were not available for production of briquettes on a larger scale, we have devised a type of bull-drawn roller in which twin rollers are set at an angle so as to combine the shearing and crushing action such as occurs in an edge-runner mill. Strong, mechanically sound briquettes have been consistently produced by this simple means.

The experiments described above were carried out in 1942 and concluded the first part of our inquiry. We have since been filling in the gaps with a long series of fairly obvious multi-factor experiments of which the results will be published later. In 1943 some 1,000 tons of charcoal-pitch briquettes were produced, under the direction of Mr. J. Smith, chief conservator of forests, in a first attempt to use the process on a larger scale, but the briquettes disintegrated when used in main-line locomotives and had to be burned in less severe conditions. With extemporized equipment, unskilled labour and limited supervision it is difficult to turn out large amounts of a good and uniform product. Charcoal burning is now being increased, and a small briquetting factory, embodying normal industrial equipment, is in operation. In this a mixture of charcoal (85 parts) and Mexphalte *DH* 75/85 (15 parts) is steam-heated and pressed between rollers, gum and oil being omitted. The product is strong and waterproof and does not disintegrate in the fire-box. Owing to formation of clinker, however, locomotive fuel trial results have been poor (equiv. evap. 5·08, 4·95). This difficulty probably arose from use of dirty charcoal and therefore should soon be eliminated or reduced.

Our thanks are due to the General Manager, Sudan Railways, for help in the well-equipped Atbara workshops and for the skilled and willing co-operation of his staff. We are also indebted to Dr. A. J. Henry, Government analyst, for determinations of calorific value.

# RESEARCH PROGRAMME FOR SOUTH WALES

IN an inaugural address to the South Wales Institute of Engineers at Cardiff on January 20, on "Industrial Planning and Research: Catchwords or Realities?", Dr. F. J. North emphasized that our plans for the expansion of industry and for the betterment of social conditions will be useless unless the availability of the means for giving effect to them has been assured. What is technically possible is not necessarily economically profitable; the success of a venture depends on a market as well as upon raw materials, and the value of one industry is related to its effect upon others. The single-track approach to many of our problems, Dr. North said, is largely due to the gap which exists between scientific knowledge and popular comprehension of it, a gap which will only be permanently bridged when a new attitude towards science is adopted by those responsible for

the educational system of Great Britain. Discussing particular proposals such as coal and its hydrogenation, the Severn Barrage scheme and the like as contributions to Welsh reconstruction, he pointed out that such questions cannot be considered solely in terms of regional standards or local expediency. The first step in giving effect to plans for social betterment in all its aspects is to make the nation realize the extent to which its welfare depends upon coal, upon those who make it available for use, and upon those who attempt to discover how best to use it.

After reviewing the position of coal in the economic picture, Dr. North discussed the aims and objects of research. He deprecated the distinction between fundamental and industrial research as helpful neither to science nor to industry, and emphasized that research is a continuous process in which one step prepares the way for another. In the past, largely because of the abundance of the world's natural wealth to which Great Britain has access, industry in general prospered without much recourse to the results of research, but now as a nation we have to recognize the desirability of doing willingly in peace-time some of the things we are doing under compulsion in war-time. The only way to ensure a future adequacy of research is to create conditions affecting remuneration, prestige and equipment, in which research will be an attractive career, while those concerned with the commercial side of industry must be encouraged to develop a scientific outlook which will enable them better to appreciate and to respond to changes in the availability of raw materials, in public taste, and in technical possibilities. Dr. North urged that the right line of advance is to extend the existing facilities by more generous appropriations to the Department of Scientific and Industrial Research, more generous grants to the universities and more generous support from firms and industries that have not yet accepted their full share of the burden. Closer collaboration between research organizations is also required, and while there are in South Wales all the necessary elements for concerted research in the interest of local industry, there are few signs of general co-ordination. He believes that regional commissioners for the co-ordination of research might help those concerned in the industries of such a well-defined area to know what has been done or is contemplated, and at the same time keep the appropriate government department aware of the collective needs of the area.

In regard to a research programme for South Wales, Dr. North considers that a prime necessity is the vigorous prosecution of the survey of the chemical and physical properties of all the coal seams, and the completion of the geological re-survey of the coal-field. The chemical information would indicate the nature and distribution of the various kinds of coal present, and the geological survey would indicate where and under what conditions they can be mined. Given a fair idea of the trend of industrial development, it would be possible to pay special attention to mining methods appropriate to the kinds of coal likely to be in greatest demand, and to the size and degree of purity of the coal. Co-ordinated work of this kind would help the mines to meet the increasingly exacting demands of industry; but mining research should also be encouraged to indicate the coals which can be most safely and cheaply won, leaving to industry the onus of finding efficient ways of using them. Knowledge of the varieties of coal and their potentialities must be the basis of any attempt to explore the possibilities of the underground gasification of coal, as well as of decisions concerning the kinds of new industry that can be developed and the localities in which they should be founded. Such decisions, in turn, afford guidance to those concerned in determining the position and character of new housing schemes, the facilities for access to them and the amenities required. Again, South Wales cannot afford to be unconcerned at the general lack of official interest in geological exploration, since its industries require minerals and ores not locally available.

Dr. North suggested that the basic principles should be to develop industries in which there is the greatest possible difference between the value of the raw materials used and that of the commodity or article produced, and in which the largest possible part of that difference is represented by payments to those whose services have effected the difference. Scientific and technical workers must be the guides and not the tools of the politician and financier, and the industries selected for foundation or expansion should be those which can be self-supporting at least within a reasonably short time. We should think along the lines of organic evolution, in which there is a continual reaction to changing environment by organisms which possess, in some degree, the capacity to modify or control it. An important function of the South Wales Institute of Engineers is to help create public awareness in matters appertaining to the industrial future of the region.

## INDUSTRIAL FATIGUE AND ABSENTEEISM

THE Industrial Health Research Board has issued a pamphlet (London: H.M. Stationery Office. 3*d*.) giving a survey in non-technical language of the problems of absence from work and prevention of fatigue. Merely vague statements about the excessive amount of absenteeism are valueless. It is necessary to know how much there is, to what extent it is greater than in peace-time and the conditions leading to it.

The Industrial Health Research Board has been studying the problem throughout the war years in numbers of factories of varying size and kind, and the records have been analysed. In normal times, it was usually estimated that absence should not exceed five per cent of the possible hours of work a year. During the war years, this amount has increased and is now between six and eight per cent for men and between ten and fifteen per cent for women. There are considerable variations from factory to factory. Factories of recent growth, situated far from the homes of those who work in them, employing women unused to factory work, show an absence-rate almost twice as high as some of the old-established works within easy travelling distance of the workers' homes.

In most factories it was found that the women lost about twice as much time as the men, and married women lost up to three times as much as single women. The conditions conducive to absence include excessive hours of work, bad working conditions, unexplained idle time, wages problems, lack of co-operation between managers and workers. The factory, however, is not the whole environment of the worker; conditions outside the factory also play a part. Some of these refer to transport difficulties,

shopping, housework and children, as well as the presence on leave of husband or son. There must also be considered the less obvious but important conditions that affect the body and the mind of the individual worker; for example, boredom, lack of understanding of the value of his work, anxiety, ill-health. As much care should be taken of the health of the industrial worker as is taken of the health of the men and women in the Fighting Forces.

The accumulated effects of war-time conditions have caused in many workers a state vaguely labelled industrial fatigue, of which one expression is in absenteeism.

During a war it is impossible to avoid making heavy demands on people's energy; but it should have been possible, if adequate use had been made of the available knowledge, to have prevented some of the worst effects. Unfortunately, for diagnostic purposes the effects of fatigue and those of boredom are similar, namely, lowered output, inferior quality of work, increase of accidents, discontent, and some physical symptoms of ill-health. Fatigue and boredom also affect one's attitude to the work and to the War. The over-tired or very bored worker becomes despondent or indifferent, and tends to lose his sense of proportion in regard to himself and his surroundings, as well as to the course of the War. The remedies are not really difficult to deduce or to make effective.

The weekly hours should not exceed 60 for men and 55 for women, and even these are too high for certain classes of work. The week-end break is important. There should be adequate rest pauses within each spell of work. Attention should be given to the design and speed of machines, and to the selection and training of people for the jobs they are best fitted to undertake. Good working conditions including canteens, and rest and recreation rooms, help to decrease fatigue and boredom, and music is a very popular antidote.

The pamphlet is most attractively printed, produced and illustrated.

## NATURAL HISTORY OF THE MINNOW

Miss Winifred Frost has done good work on the biology and natural history of the minnow *Phoxinus phoxinus* (*J. Animal Ecol.*, **12**, No. 2; Nov. 1943). Taking Lake Windermere and one of its affluent streams, the River Brathay, as headquarters, the minnow has been studied in detail for two years. The investigation deals with its habits, growth, food and reproduction. Minnows are active and pelagic in both lake and stream from April until October, and migrate into deeper water where they are relatively passive and hidden under stones from November to March. They breed from May until July, sexual maturity in a few being reached at the end of the first year: the majority of those in their second year and all older fish are mature.

Length frequency curves supported by scale examination indicate that there are certainly three-year classes, and suggest the possibility of a fourth. The feeding habits have been studied intensively and it is found that in the lake, although a variety of food is taken, planktonic Crustacea, particularly Cladocera, form the chief food and these are also much eaten by the other fish. The supply of these organisms is, however, so large that it seems unlikely that the minnow is a serious competitor for food in this community, especially because of its inshore habits. In the river, Algæ are eaten, a much larger proportion of insect larvæ and less Cladocera and copepods. Much of the food here is similar to that of the young brown trout, and competition is likely. As to enemies, there are many, for the minnow is eaten by a few trout and many perch but not much by the pike. Eels also eat it and it forms part of the diet of the brown trout.

In Windermere and similar large lakes the conclusion is that it is unlikely that the minnow is a serious competitor for food, and it is of itself an appreciable source of food for larger fish. In running water inhabited primarily by salmon and trout the possibility of serious competition is great. So far as fishery conservation is concerned it is concluded that in general, provided the fish population is balanced with active predators to keep their numbers in check, it may be said that minnows are not inimical to a fishery. If, however, the balance is disturbed in favour of fish such as salmon and trout to the exclusion of the more active predatory fish, the minnow may multiply and become a menace.

## JUTE STUDIES

Recently there have been several Indian publications upon the anatomy of jute (*Corchorus*) with special reference to the fibre production and development. Such studies are to be welcomed as affording a basis for the practical improvement of varieties and for modification of extraction and preparation methods.

An earlier paper by Prof. B. C. Kundu (*J. Indian Bot. Soc.*, **21**, 93; 1942) has been followed by Agricultural Research Memoir No. 1 from the Indian Central Jute Committee. This confirms the work of Kundu in the main particulars, though the authors, S. S. Ghosh, K. R. Rao and J. S. Patel do not agree that the original protophloem of jute is secondary in origin. Discrepancies here may be associated with the age of the shoot apex examined; certainly Kundu's figures of the early procambial strands are striking in their demonstration of the early growth being entirely by longitudinal divisions, though it may not necessarily be solely with radial seriation as in the case of cambial activity.

In *C. capsularis* these authors record the presence of a distinct periderm, not seen by Kundu, much of whose material was grown under greenhouse conditions in England; the authors note how this periderm, as also the free development of adventitious roots at the base of plants frequently flooded during growth, may prove a deleterious influence upon the ready separation of the fibre during retting.

As Agricultural Research Memoir No. 2, Messrs. J. S. Patel and S. S. Ghosh have published a preliminary study of the anatomy of retted jute. These studies have shown how progressive the isolation of the fibre strands may be; thus they may be free in the top portion of the stem in five-six days, in the middle of the stem in nine-twelve days and at the base only after fifteen-twenty days. Heavily lignified fibres resist retting, while near nodes, injuries, etc., retting is usually delayed (this was exemplified, in the case of nodes, in some photographs communicated by J. H. Priestley to the late Dr. S. G. Barker, *J. Textile Inst.*, **30**, 273; 1939). These retting studies contain some preliminary notes on retting organisms; but these need extension by isolation and culture of the organisms by the usual methods.

# FORTHCOMING EVENTS

## Thursday, July 6—Sunday, July 9

BRITISH RHEOLOGISTS' CLUB (at St. Hilda's College, Oxford).—Conference.

**Friday, July 7**

10 a.m.—"Rheology of Large Deformations and Plastic Flow", (*a*) Plasticity of Metals; (*b*) Polymers; (*c*) The Liquid State.

2.15 p.m.—"Relations between Shear, Tension and Compression in Complex Bodies (The pi-problem)".

5 p.m.—"Some Rheological Applications to Medical Science".

**Saturday, July 8**

10 a.m.—"Rheological Nomenclature and Symbols Metallurgical and Non-Metallurgical".

8.30 p.m.—"Future Organisation of Rheology".

## Tuesday, July 11

QUEKETT MICROSCOPICAL CLUB (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Exhibition of specimens and discussion.

## Thursday, July 13

SOCIETY OF CHEMICAL INDUSTRY (joint meeting of the LONDON SECTION and the INSTITUTE OF METALS) (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 7.30 p.m.

## Friday, July 14

SOCIETY OF CHEMICAL INDUSTRY (at the Royal Institution, Albemarle Street, London, W.1).—Sixty-third Annual Meeting. At 11.30 a.m.—Presidential Address. At 2.45 p.m.—Prof. A. V. Hill, F.R.S.: Messel Medal Address.

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. J. Proudman, F.R.S.: "The Tides of the Atlantic Ocean" (George Darwin Lecture).

# APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT LECTURER or LECTURER IN PHYSIOLOGY—The Secretary, King's College, Strand, London, W.C.2 (July 11).

MISTRESS or MASTER to teach MATHEMATICS in the Junior Technical School of the Selby Art School and Technical Institute—The Secretary to the Managers, Education Office, Garforth, near Leeds (July 11).

CITY ELECTRICAL ENGINEER AND MANAGER of the Carlisle Electricity Undertaking—The Town Clerk, Town Hall, Carlisle (July 12).

ASSISTANT MASTER to teach ENGINEERING DRAWING, ENGINEERING SCIENCE, and WORKSHOP TECHNOLOGY up to the standard of the Ordinary National Certificate in Mechanical Engineering, in the Redditch Technical School—Mr. G. Brodrick, Education Office, Church Green West, Redditch (July 12).

DEPUTY BOROUGH ENGINEER AND SURVEYOR AND DEPUTY PLANNING OFFICER—The Borough Engineer and Surveyor, Town Hall, Barking, Essex (July 13).

ASSISTANT MASTER (temporary) to teach SCIENCE SUBJECTS, principally CHEMISTRY and MECHANICS, in the Junior Technical School—The Director of Education, City Education Offices, 33 St. David's Hill, Exeter (July 14).

ASSISTANT VETERINARY INVESTIGATION OFFICER at the University of Bristol Agricultural Advisory Centre—The Secretary and Registrar, The University, Bristol (July 14).

ELECTRICAL ENGINEER (temporary)—The Clerk to the East Grinstead Urban District Council, Norton House, London Road, East Grinstead, Sussex (endorsed 'Temporary Electrical Engineer') (July 14).

BURSAR to the Queen's College, Oxford—The Provost, Queen's College, Oxford (July 15).

SPEECH THERAPIST—The Director of Education, Shire Hall, Nottingham (July 15).

ASSISTANT LECTURER AND DEMONSTRATOR (woman) IN ZOOLOGY—The Principal, Royal Holloway College, Englefield Green, Surrey (July 15).

MAN or WOMAN to teach GEOGRAPHY and ELEMENTARY MATHEMATICS in the Mexborough Schofield Technical College—Mr. E. B. Stockdale, Education Office, Mexborough, Yorks. (July 15).

LECTURER (temporary) IN MINING, a LECTURER (temporary) IN MINERAL DRESSING, and a LECTURER (temporary) IN ENGINEERING—The Professor of Mining, Royal School of Mines, Prince Consort Road, London, S.W.7 (July 15).

LECTURER IN GEOGRAPHY—The Principal, Borough Road College, Isleworth, Middlesex (July 17).

DEMONSTRATOR (man or woman) in the Department of Inorganic and Physical Chemistry—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1 (July 17).

GRADUATE or equivalent in MECHANICAL and/or ELECTRICAL ENGINEERING, and a GRADUATE IN SCIENCE to teach Science in Lower Forms, together with some General Subjects, in the Bridgend Mining and Technical Institute—The Director of Education, County Hall, Cardiff (July 17).

MASTER or MISTRESS (temporary, full-time) to teach MATHEMATICS and SCIENCE to Junior Technical students, ARITHMETIC to Junior Commercial students, and SCIENCE to Catering students in the Harrogate Technical Institute—Mr. W. E. C. Jalland, Secretary to the Managers, Municipal Offices, Harrogate (July 17).

ENGINEER to the Eden Catchment Board—The Acting Clerk to the Eden Catchment Board, The Courts, Carlisle (July 19).

GRADUATE LECTURER IN ELECTRICAL ENGINEERING at the Lincoln Technical College—The Director of Education, City Education Office, 4 Lindum Road, Lincoln (July 19).

DIRECTOR OF THE OTAGO SCHOOL OF MINES (University of Otago)—The High Commissioner for New Zealand, 415 Strand, London, W.C.2 (July 21).

LECTURER IN EXPERIMENTAL PHYSIOLOGY—The Registrar, The University, Sheffield (July 28).

JOHN RANKIN CHAIR OF GEOGRAPHY—The Registrar, The University, Liverpool (July 31).

W. H. COLLINS PROFESSORSHIP OF HUMAN AND COMPARATIVE PATHOLOGY—The Secretary, Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C.2 (July 31).

SENIOR LECTURESHIP IN THE DEPARTMENT OF METALLURGY of the University of the Witwatersrand—Dr. W. Cullen, 4 Broad Street Place, London, E.C.2 (July 31).

FOREST ENGINEER for the Sierra Leone Government Forestry Department—The Secretary, Overseas Manpower Committee, Ministry of Labour and National Service, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. 1114).

DAIRY CHEMIST (University Honours Graduate, with Bacteriology training)—The Technical Office, Milk Marketing Board, Thames Ditton, Surrey.

LECTURER (woman) IN EDUCATIONAL PSYCHOLOGY—The Principal, St. Katharine's College (Liverpool), at Queen's Hotel, Keswick, Cumberland.

GRADUATE ASSISTANTS (two) qualified to teach MATHEMATICS, SCIENCE and ENGINEERING DRAWING in the Junior Technical School and National Certificate classes, at the Ashton-under-Lyne Technical School—The Director of Education, 8 Warrington Street, Ashton-under-Lyne, Lancs.

MASTER or MISTRESS for MATHEMATICS, and a MASTER for ENGINEERING SUBJECTS—The Principal, Erith Technical College, Belvedere, Kent.

## RESEARCH AND COLONIAL DEVELOPMENT

GIVEN a sufficiently detached perspective of the inception and trend of British Colonial development, one might well form an impression not differing greatly from that proceeding from a survey of the workings of human nature. There would be disclosed to one's view such elements as curiosity, adventure, courage, need, opportunism, foolishness, erratic behaviour, much remissness, and unwise discontinuity of effort ; but there would also be evident a real tenacity of purpose, a growing element of perception and constructiveness, together with a willingness to recognize past mistakes, and, not least, a determination to make good in the future. Those who are familiar with almost any one of our Colonies will be able to fill in the details of the mixed and not always laudable historical scene.

Whatever a review of the past may disclose, the keynote to the future is evident. In almost every Colony there is much to be done. The general problem of Colonial improvement is not a simple one : in each territory, according to its particular character, there are to-day many matters requiring more or less simultaneous consideration ; and the same holds good for these territories taken collectively. So the clamour for action arises on all sides. As obviously everything cannot be begun at once, those responsible for the administration of programmes of research and for welfare schemes have to face the questions : How to begin, and where ? A partial answer to these questions is given in two official documents just issued*.

In the First Annual Report of the Colonial Research Committee, some of the research schemes already approved are set out, together with a general survey of the fields that await attention. These last include topographical and geodetic surveys, geological research, fisheries, agriculture, animal health and forestry, medical research, the social sciences, industrial and archæological research. Not least, the important consideration of creating a cadre of men of science versed in Colonial problems is already being implemented by the institution of twenty-five Colonial research fellowships. This wide casting of the net and generous appreciation of what should be attempted through the medium of research towards the welfare and advancement of the Colonial Empire, at a period when the war effort is rising to its climax, is surely to be commended. Not only are these activities in our best administrative tradition, but coming at this particular time they should also do more than almost anything else to indicate to the outside world something of the essential national attitude to our overseas possessions.

It is true that these matters are for the most part still at the exploratory stage. But while any undue delay is to be deplored, the launching of new and

* Colonial Research Committee; First Annual Report 1943–44. (Cmd. 6535.) (London: H.M. Stationery Office, 1944.)
Colonial Development and Welfare Act, 1940. Return of Schemes made under the Colonial Development and Welfare Act, 1940, by the Secretary of State for the Colonies with the Concurrence of the Treasury in the Period from 1st April 1943 to 31st March 1944. (Cmd. 6532.) (London: H.M. Stationery Office, 1944.)

costly ventures without sufficient initial consideration would be not less harmful. Broadly speaking, the Committee has been concerned with two main aspects: first, with a review of the various fields of research together with a consideration of the central, regional and local organization required to deal with them; and secondly, with a scrutiny of specific schemes submitted for consideration.

In reviewing the general position, the Committee has been impressed with the need for providing, for each main branch of science, a co-ordinating centre to which proposals for research in that branch can be referred for expert scrutiny. "The Committee have therefore favoured the establishment of specialist Research Committees or Councils, which, in addition to being available for the provision of advice to the Secretary of State, would be in a position to be in direct communication with individuals, institutions or teams at work in the Colonies and so help break down the isolation noted in the Progress Report as a disadvantage suffered by Colonial research workers in the past."

As to the preparation of research programmes and decisions on priorities, the Committee has had to deal with the initial question of the distribution of responsibility and function between "the centre and the field, between London and Colonial Governments". It is recognized that no simple or uniform answer is possible. The various research councils and the Committee will serve in a purely advisory capacity to the Secretary of State: any authority in particular matters, such as the administration of a particular scheme, would be delegated by the Secretary of State or with his concurrence by some Colonial Government. The regional organization of research —a desirable feature—is also under consideration.

To those who rightly cherish and uphold the essential quality of freedom in science, the emphasis on planning and on the centralized scrutiny of research projects may perhaps raise doubts as to the general outlook. This issue is dealt with as follows: "The Committee feel bound to point out that whereas, rightly handled, regional organizations of this nature hold out excellent promise for good work and for a harmonious co-operation between workers in the field and the organizations which are being built up at the centre, it might also be possible by wrong organization to impede the flow of research which is the object of all. In their opinion, the conditions of success for the fruitful application of research to Colonial needs lie in the achievement and maintenance of a due balance between the greatest possible freedom of activity on the part of the research workers themselves, whether as individuals or as teams, and the proper allocation of the available resources of all kinds to the solution of the most urgent problems."

This attitude, if it can be maintained in practice, would appear to be sound. In all these anticipated developments one thing stands out clearly—the importance, at all levels, of securing the best men for particular jobs. This is recognized by the Committee. Whatever decisions may be reached as to the relations between central and regional organizations, between administrator and research worker, "the arrangements should be such as to attract and retain the services of research workers of adequate calibre. To this end, such workers should not feel that by working in and for the Colonies they are in any danger of falling behind the progress of their sciences, or of losing their chances of advancement therein. They should be able to maintain the freest possible contact with the advancement of science and with such institutions as exist, or may be created, for the co-ordination and dissemination of new knowledge. Furthermore, these workers must not be inhibited from working in the way best calculated to allow them to achieve the most valuable results, which means, in the field of scientific research as much as in any other sphere of creative activity, allowing the worker the greatest possible latitude as to his methods of work. Complete freedom of enquiry is not the only, but it is an essential, condition of fruitful research work." This aim of recruiting men of real talent, and of giving them freedom, scope, and reassurance as to the future, should be the subject of the widest publicity in all the universities and other educational institutions of Great Britain. Given such men, imbued with the ideal of service, we may look with confidence to a future fruitful in results.

The Report rightly directs attention to the part which local peoples may play in planning and guiding researches intended to enhance their own well-being. This would usually be done through Colonial Governments. Without doubt, one of the means of creating and maintaining an interest in research, and in due course of putting its findings into practice, will be to have work actually in progress in the territories concerned, and wherever possible to seek co-operation with interested local bodies. In this matter, the highly developed tradition of hospitability in Colonial life should do much to smooth the way.

The new Colonial research fellowships which are to be offered will almost certainly command wide attention and create stirrings in the minds of young men, who, after a longer or shorter spell of research at a university or kindred institution, may wish to adventure abroad. The aim is to create a cadre of men of science versed in Colonial problems. Many good results should follow the launching of this scheme; not least, the horizon of the scientific world will be enlarged by being familiarized with Colonial problems and the opportunities they afford for new lines of work. These fellowships will be "open to qualified scientists, whether in the natural or in the social sciences, to enable them to pursue research work in the Colonial Empire. The Fellowships will normally be for two years, and the Secretary of State hopes that Universities and other research institutes will be willing to grant applicants, if already members of their staffs, leave of absence for this period in order to enable them to take up the fellowships. Provision has been made for twenty-five such Fellowships within the next five years. It is recognized that war-time shortages of personnel will restrict the immediate applicability of the scheme; it is, however, being brought into force immediately, in case there are suitable candidates in any part of the Empire who are not at present required for urgent war-time work."

It may be said that the Research Committee takes a modest view of its activities. "The Committee are conscious that the list of specific researches approved since their Progress Report is short, and they would not wish it to be understood that they consider that the present rate of progress would be satisfactory in normal circumstances. But conditions are not normal, and, moreover, the Committee have been impressed by the fundamental importance, if a proper rate of progress is to be achieved when normal conditions return, of a sound basic organization. They have felt justified, therefore, in devoting the greater part of their attention to the problems of organization which have been described in this report."

The second document gives an idea of the many and varied schemes, including research, welfare and development, which have already been approved and are being financed (by free grants and loans) under the Colonial Development and Welfare Act (1940) up to March 31, 1944. Here the extent of support given to specific projects is set out. Food production, road-making, irrigation, agricultural development, water supplies, medical and health services, education, mosquito control, airfield construction, are only a sample of many items. Taken together, they afford a vivid impression of how vast and varied are the Colonial commitments of Britain and how much needs to be done, sometimes to make good overdue omissions, at other times to prepare for a brighter and better future. The battle with the tropics, which is unrelenting and has to be fought on many fronts, calls for all the weapons at our command. It is good to know that reinforcements are on the way.

## EXPERIMENT AND THEORY IN PHYSICS

Experiment and Theory in Physics
By Prof. Max Born. Pp. iv+44. (Cambridge: At the University Press, 1943.) 2*s*. net.

THE question of the relation between theory and experiment in physics is one of perennial interest. It is, of course, only one aspect of the fundamental philosophical problem of the general relation of the rational to the empirical, and it is not too much to say that the peculiar character of progress in physics during the last generation has made it, for the time at any rate, the most important aspect of that problem. Certainly no one can contemplate the development during this century of both macroscopic and microscopic physics—relativity and quantum theory—without realizing that, whether or not his philosophical outlook has been modified thereby, its most appropriate expression must be very different from any which was possible previously.

We can no longer accept unquestioningly the naïve view that we are gradually learning the secrets of an objective world which exists in complete independence, undisturbed by our inspection and apprehension of it. We are bound to recognize that our activities, in theoretical physics at least, are not so much those of discoverers of unknown lands as those of creators of works of art. We do not look for the 'reality' behind experience, but seek to create a language in which the relations between our experiences can be most comprehensively and elegantly expressed. The statements of these relations are our 'Laws of Nature', and the question presents itself: Are these laws deducible only from experience itself, or are they *necessary* relations which could have been formulated, and recognized as relevant to experience, by a sufficiently powerful intelligence from pure reason alone, without reference to experience? The question, be it noted, implies the independence of reason and experience, for it contemplates the possibility that a being without experience might still reason effectively. We can evade any psychological objection that might be made to this assumption by supposing, if necessary, that our reasoner has had his reasoning faculties created or sharpened by experience which he has then completely forgotten. The question then remains: Could he formulate relations, to which any physical experience which he might afterwards acquire must conform, those relations being of the kind which we usually call laws of Nature and have in the past believed not to be derivable by reason alone?

The great majority of physicists, I believe, would answer this question in the negative, though they might be prepared to admit that the present formulation of physical laws owes more to reason and less to experience than we have been accustomed to assuming. Two outstanding thinkers, however—Sir Arthur Eddington and Prof. E. A. Milne—have independently given an affirmative answer. They do not necessarily deny the value of experience as a practical device for deriving the laws, or the possibility of factual details of experience which the laws cannot foretell; nor do they claim the perfection of intelligence needed for the rational deduction of the supposedly inevitable relations, though they do proceed some distance along the logical path and describe it quite differently. But they agree in asserting that the whole scheme of physical law, in an ultimately complete form, is attainable by reason alone, and so resurrect a type of philosophy which the scientifically minded since the time of Galileo and Newton have regarded as completely and irredeemably annihilated.

This phenomenon is justifiably regarded in many quarters with some apprehension, but even the darkest cloud has a silver lining, and when we read in Prof. Max Born's admirable little booklet that he has been induced to write it from his conviction that the ideas of Eddington and Milne are a considerable danger to the sound development of science, we are inclined to grant that the wayward astronomers might after all be forgiven, since their doctrines have produced so happy an issue. Prof. Born is in an almost unique position to write on this subject. Not only has he contributed some of the most vital ideas to modern physics, but also he has been in close touch with nearly, if not quite, all those others who have helped to create the atmosphere in which the philosophy of Eddington and Milne has been able to develop. He is thus both well aware of the measure in which the originators of the new ideas regard their work as dependent on experience, and particularly competent to form a trustworthy judgment on the general question. His conclusion is this: "I believe that there is no philosophical high-road in science, with epistemological signposts. No, we are in a jungle and find our way by trial and error, building our road *behind* us as we proceed. We do not *find* signposts at crossroads, but our own scouts *erect* them, to help the rest."

The course which Prof. Born follows is that of showing "the mutual relationship between theory and experiment in the actual historical development of science". After a brief introduction on the empirical character of geometry and astronomy and of the "experimental philosophy" of Galileo and Newton, he examines the more modern ideas which at first sight appear to have had an *a priori* origin. The various 'minimum' principles such as that of least action, Maxwell's electromagnetic theory, general relativity, matrix mechanics, wave mechanics, thermodynamical statistics, are discussed in turn, and the parts played in their development by theory and experiment are illustrated. Attention is then directed more specifically to the theories of Eddington and Milne, and the author arrives finally at the conclusion stated above. The writing is clear and vivid, and is interspersed with personal reminiscences and illuminating analogies.

To attempt a more detailed précis of this fascinating paper would be to weaken it; it should be read in its entirety. A more fitting commentary would be a brief discussion of a few of the points which its perusal suggests. Prof. Born hits the nail on the head when he says, on pp. 8–9, "The problem of physics is how the actual phenomena, as observed with the help of our sense organs aided by instruments, can be reduced to simple notions which are suited for precise measurement and used for the formulation of quantitative laws". If that is so, then it naturally follows that the production of equations out of our inner consciousness is something different from a solution of the problem of physics. Let Eddington and Milne give birth to their equations and, if they will, suggest a distinctive name for the activity in which they are engaged; nothing more need be said on the matter. Unfortunately, however, we tend unconsciously to forget this simple and accurate definition of physics, and fall back on the older, discredited assumption that there exist, independently of our experience or our reasoning, certain objective, self-sufficing things called 'Laws of Nature', and that experience and pure reason are alternative instruments by which, in physics, these laws of Nature may be apprehended. Even Prof. Born seems at times to lapse into this attitude, notably in the earlier portion of his essay. From that point of view we can argue until doomsday whether reason or experience is the better instrument, and no one will be a penny the better. If, instead, we simply use our reason to organize our experience into quantitative laws, all such argument is seen to be irrelevant, and we become physicists again.

A suggestive line of thought is opened up by the remark on p. 18 that "Heisenberg felt that quantities which had no direct relation to experiment ought to be eliminated". We must, of course, accept Prof. Born's statement about Heisenberg's feelings, for he and Heisenberg worked together on the problem referred to, but as a general rule the restriction to quantities *directly* related to experiment is surely too drastic. Probably the first consciously realized application of this principle, in modern physics at least, was that of Einstein to the question of motion through the ether. Here the earth had been assumed to have a definite, though unknown, velocity, and the value of Einstein's achievement lay in his recognition that because, by no experiment that could be devised, could this velocity be unambiguously determined, the existing scheme of physical concepts should be reformed so that this inaccessible quantity should no longer appear to have any significance. The justification for this reform, however, lay essentially in the fact that the earth's velocity could not be determined by *any* means. If it could have been found, by however tortuous a process, without introducing any contradiction into theoretical physics, the special theory of relativity would have fallen to the ground. No one would have been obstinate enough to ignore the value obtained because a series of metre rods had not been nailed to the ether along the earth's orbit and the hour angles of the mean sun observed when the earth coincided with its successive marks.

The only acceptable 'operational' principle in physics is that which demands that every concept used shall be related, in a strictly specifiable way, to possible measurements. Any narrower requirement than this leads to absurdity. Consider, for example, Avogadro's number. This is definitely related to experiment, for its value has been experimentally determined. The relation—to take one determination as an example—is that if one makes all the measurements involved in determining the temperature and density of a liquid and its vapour at an observed pressure, and the viscosity of the liquid, and combines the results in a particular way into a complicated expression, the value of this expression turns out to be a large number which is approximately the same for various gases. This we call 'Avogadro's number', and denote by the letter $N$. It is a perfectly legitimate concept because it is related to experiment through the measurements referred to. But now, when we introduce a particular hypothesis, namely, that a gas consists of a multitude of similar small moving particles called molecules, which are responsible, through the type of behaviour which we assign to them, for the pressure, temperature, etc., that we measure, we find that the pursuit of our ideas leads us to identify $N$ with the number of molecules in unit volume of a gas. The direct experimental determination of a number of molecules, however, consists of a process of counting them, and this is impossible. Hence, if we define $N$ as a certain power of the reciprocal of the kinematic viscosity per unit . . . per unit . . . etc., it is directly related to experiment; but if we define it as the number of molecules per unit volume of a gas under standard conditions, it is not. Heisenberg's feeling, then, should lead him only to substitute a cumbrous for a simple name, while leaving the practice and the mathematical structure of physics unchanged. It is difficult to regard such an achievement with admiration.

In considering the legitimacy or otherwise of a physical concept, we must, then, ignore all hypotheses or theories which give a picturable significance to the concept, and take into account only its relation to actual operations of measurement. The hypotheses may be, and in practice are, essential for making progress, but they have no bearing on the question whether the concept may be used in physics or not. For this reason I find it difficult to agree with Prof. Born's view that operational definition "comes to grief in quantum theory". It is true that in that theory symbols are used of which we have not been able to give picturable correlatives, though Prof. Born's own invaluable interpretation of one of them as representing a probability should remind us that this is not necessarily a permanent characteristic. But an operational definition is not identical with a picturable metaphor; it is simply an expression of

the relation of the mathematical symbol, in its mathematical context, to measurable quantities, and this is possible in quantum theory as in any other part of physics. The remoteness of the relation has nothing to do with the matter, and may in any case disappear overnight when someone thinks of a new analogy.

Milne's claim that his theory obeys the operational principle raises objections of somewhat different character. In so far as an operation can be described which, if carried out, would yield numbers for the symbols he employs, those symbols may be said to be operationally defined. The trouble is that, for practical reasons, we can get no further than a description of the operations; actually to perform them we should require infinite time, an infinite army of slaves or disciples whom we could transport where we wished, and apparatus of infinite delicacy, to say nothing of the absence of any unsuspected difficulties throughout the great distances and durations involved. This would be of little consequence if it prevented only the final verification of a theory made probable by other observations, but in Milne's theory it is the very first requirement. Until these impossible demands are satisfied, physics cannot begin. Any agreement with observation that the theory might claim must therefore be obtained by departing from the operational definitions. Many, like Prof. Born, will "not wish to discourage anybody who feels in himself the vocation to embark on so adventurous a journey", but they will themselves prefer to see what can be done with measurements that can not only be conceived but actually made.

Like others, Prof. Born has not succeeded in understanding the essential parts of Eddington's theory connecting the constants of quantum theory with those of cosmology. That is not to say that there is nothing of great value in the theory. His final comment is perhaps the wisest that has yet been made on this subject: "I am far from attacking Eddington's theories or from doubting his results. If they should turn out to be right I shall rejoice. But I shall not attribute this (possible) success to Eddington's philosophy, as a doctrine which could be followed by others, but to his personal genius and intuition." HERBERT DINGLE.

# POLLEN ANALYSIS

## An Introduction to Pollen Analysis

By Dr. G. Erdtman. (A New Series of Plant Science Books, Vol. 12.) Pp. xvi+240. (Waltham, Mass.: Chronica Botanica Co.; London: Wm. Dawson and Sons, Ltd., 1943.) 5 dollars.

POLLEN analysis is the term applied to the quantitative analysis of material containing pollen, by microscopic recognition of the species and genera of plants from which the pollen came. The pollen membranes have qualities of shape, size, surface, and structure which permit these identifications, and their preservation is often excellent.

It was G. Erdtman, a Swede, who in the nineteen-twenties, by a series of papers written in English, introduced British and American scientific men to the principles and technique of pollen analysis, a new method of geological inquiry which had recently been developed in Scandinavia, particularly by the energy and insight of L. von Post. The succeeding years have seen a very great extension of the applications of pollen analysis. Not only has it been used in countries in all parts of the world to elucidate their forest history, and thence the drift of former climatic conditions, but also it has been shown to afford the means of solving an unexpectedly wide range of problems. Thus, by the analysis of ice in the various layers of the great alpine Aletsch glacier, Vareschi has been able to recognize the regular seasonal alternation of preserved pollen, and on this basis has made important deductions about the character of glacier structure and movement. In the Swiss Alps, in the eastern United States, and recently in South Wales, analyses of the pollen content of the air at different seasons have proved valuable in studies of hay-fever.

It has long been recognized that dating of prehistoric objects and structures found in lake- or bog-deposits is often possible by reference to the geochronological scale afforded by the regular drift of forest history. Similarly, the course of relative movement of land- and sea-level may be effectively dated, and eustatic effects distinguished from isostatic. More recently, it has become apparent that not only is the former distribution of natural plant communities reflected by pollen analyses, so that the conditions of salt-marsh, lake, fen, forest and bog may be accurately recognized in buried layers, but also, as Iverson has shown (see *Nature*, April 29, p. 511), the influence of prehistoric man in modifying natural communities may be detected, together with the origin of the new anthropogenous vegetation he has created.

Hitherto no text-book of pollen analysis has been available, and we warmly welcome, therefore, the appearance of the "Introduction to Pollen Analysis" by Dr. Erdtman. He has himself in the last twenty years contributed important results to the field of pollen analysis. He has developed a technique of preparation by chlorination and acid-hydrolysis which very greatly simplifies counting of grains in materials poor in pollen: he has sharpened the technique of critical recognition of species by their pollen morphology, and he has contributed much to the knowledge of long-distance flight of pollen. In this book these matters are given adequate treatment, together with such related topics as the analysis of pollen in honey as a basis for determination of the country and season of its origin, and the geological use of spore-counts in coal seams.

The greater part of the book is nevertheless devoted to description of the morphology of a wide selection of pollen grains and spores, and of these very numerous drawings are given—very usefully all upon the same scale. The types included are largely north-west European, but a sprinkling of North American and other species is also included. The atlas of twenty-eight plates thus provided is certain to be of the greatest value to all who study pollen analysis.

There is still much to be written of the results of application of pollen analysis to recent geology, and we may perhaps feel that this field has been a little neglected by Dr. Erdtman; but it has been his purpose to direct study to the widest scope possible, and in this he has certainly succeeded. Both he and *Chronica Botanica* are to be congratulated on the easy and natural English of the book: many others deserve credit for having enabled production of the book to be carried through during a world war, with the author still in Sweden and his publishers in the United States. H. GODWIN.

# THE RUGBY EXPERIMENT

## From Learning to Earning

Birth and Growth of a Young People's College. By P. I. Kitchen. Pp. 168. (London: Faber and Faber, Ltd., 1944.) 8s. 6d. net.

THE establishment in due course of young people's colleges having almost become the law of the land, this book could not have appeared at a more opportune moment. In a general way, the story it tells is well known. In a couple of years, the day continuation school clauses of the Act of 1918 became, at any rate in the sense in which their author meant them, a dead letter—except at Rugby. The story with its sequel is here set forth by Mr. Kitchen, who since 1919 has been principal of Rugby College of Technology and Arts, and organizer of further education at Rugby. He describes his book as a simple account of a small-scale experiment for assisting youth in its dangerous crossing over the no-man's land between school and work,' and he hopes its realism may prove a refreshing contrast to the chorus of reconstruction programmes now emanating from the idealists.

The Lewis Committee of 1917 reported the occupations of children of 14 plus as amounting to a small proportion of apprenticeships and a large proportion of blind-alley jobs and seasonal work—a fruitful source of juvenile delinquency. The Committee confidently recommended compulsory day continuation schools, and the recommendation was adopted by Mr. Fisher in the following year. (It may be observed that the dismal account given by Mr. Herbert Lewis's Committee in 1917 is just as true in 1944.) Appointed days were fixed in a few places, of which Rugby was one, for the operation of the clauses in the Act which made attendance at continuation schools compulsory. Rugby's appointed day was April 13, 1920, and Rugby proceeded with its preparations.

An enthusiastic staff resolved to give the go-by to the old order of marks, examinations, reports, competitions, rewards and punishments, and to create a new order in which control was to be self-control, and discipline a disreputable word. The guiding principle was free activity, and precious time was not to be wasted on vocational education. To cut a long story short, the scheme received an unexpected shock. It satisfied nobody. With employers murmuring, parents dissatisfied, public opinion uneasy, and young people themselves "overdosed with high lights, play and freedom", the programme of the compulsory day was replanned on the old lines, and freedom was reserved for voluntary evening work, where it thrived. A modern curriculum was eventually devised, of which the underlying principles will no doubt receive careful attention in many other places besides Rugby.

But Rugby's decision to stand alone as the pioneer compulsory day continuation school was likely to incur criticism and animosity, and a hard struggle ensued, especially after the promising London attempt and the Kent scheme both had to be abandoned. The school was, of course, an isolated institution, and was regarded by some as a mere curiosity, but by the more far-seeing as a possible "spring-board for a second forward movement, better timed and more carefully prepared, with a more successful issue". The author adds an account of the birth and growth of the technical and art school; and it is to be noted that the Rugby experiment is entirely favourable to the association of all forms of part-time schooling in one college building, with all types of pupils learning and growing together. "All gain much by the example of and contact with others, old or young, bright or dull, ambitious or indifferent, engineers or artists, conscripted or voluntary, scholarship or paying pupils."

The story of the Rugby experiment needed to be told, and it is most fortunate that the story has been told so worthily. The total impression left upon the attentive reader is quite clear, and there is not a dull sentence in the book. A good deal of it is a record of a real fight, a struggle for existence, in which the more enlightened employers and parents, and the practical support of the great school near by, helped to secure a victory.

T. RAYMONT.

# EVOLUTION OF A LAND POLICY

## The Arkansas Plantation, 1920-1942

By Donald Crichton Alexander. (Patterson Prize Essays, Yale University, Vol. 2.) Pp. 118. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1943.) 6s. 6d. net.

THIS ably written essay deals with far wider issues than its title suggests. It reviews the disastrous condition into which American agriculture in general, and the cotton-growing industry in particular, fell between the two World Wars, and the gradual evolution of measures to remedy this. The United States had become a creditor nation, and she failed to realize that a policy of high industrial tariffs was limiting trade with her neighbours. The tariffs maintained industrial prosperity for a time but aggravated the agricultural depression. Huge stocks of cotton accumulated and growers went bankrupt.

An account is given of the dismal failure of the Harding, Coolidge and Hoover administrations to understand and deal with the problem. Under Roosevelt, effective action was taken and an Agricultural Adjustment Act was passed; but in 1936 the Supreme Court announced that it was unconstitutional. Soil conservation had been a secondary objective in this Act, but under a new Soil Conservation and Domestic Allotment Act passed in 1936 it took first place. According to Mr. Henry Wallace, the Act had five objectives: "Preservation of soil fertility, diminution of soil exploitation, promotion of the economic use of land, the protection of rivers and harbours against the results of soil erosion and the attainment of parity income for agriculture". This Act failed as a means of acreage control, and a second Agricultural Adjustment Act was passed in 1938 in which preservation of soil resources is still a basic objective. Another interesting point is that it contains provisions designed to gain a wider market for the farmer; these include the establishment of four regional laboratories for research and development of new uses for farm products, a scheme that might very profitably be studied in Britain.

The author's easy and lucid style makes the book a pleasure to read, and in view of the difficulties through which British agricultural industry has been passing it will be of interest to many who are concerned with farming.

It is to be hoped that in framing our own agricultural policy due consideration will be given to that most important factor, the maintenance of soil fertility, and that attention will be directed to research on improved and new uses for agricultural products.

W. G. OGG.

# LIGHTNING CALCULATIONS WITH LIGHT*

By Sir LAWRENCE BRAGG, O.B.E., F.R.S.

WHEN we attempt to infer the positions of the atoms in a crystalline structure from measurements of X-ray diffraction, all methods reduce in principle to a matter of 'trial and error'. The investigator tentatively places the atoms in certain positions, using judgment and past experience to set up an arrangement which does not conflict with interatomic distances and probable groupings. He then calculates how such an arrangement would diffract X-rays, and makes a comparison with what is observed. If there is no correspondence, he must try again. By eliminating possibilities and by adjustments of any structure which shows hopeful signs of checking with observations, he finally arrives (if successful) at an arrangement which he can regard as established. All this involves an immense amount of calculation. He may, for example, make measurements of a thousand diffracted beams. For each model, he must calculate the intensities of diffraction and compare it with what is observed. When the structure is complex, containing many atoms, there are so many possible permutations and combinations of the atomic positions that considerable courage and perseverance are necessary. A structure of a new type, such as a complex silicate or an organic molecule such as a sugar, has often meant one or two years of hard work and the accumulation of drawers full of calculations. The labour is well repaid, because so often a new structure casts quite a new light on an important chemical problem. Any method, however, of reducing the labours of calculation, and so saving the time of the expert, is of value.

I wish in this account to describe some methods of making light do our calculations for us. These methods are not so precise as those of computation, at any rate as yet. They are rough and ready, but quick, and I think they are promising and may be developed into a really useful tool. It is as if we were doing an approximate sum with a slide rule, to see whether the answer is about right, before turning to the logarithm tables for a more precise calculation. I have therefore called this discourse "Lightning Calculations with Light".

## The 'Fly's Eye'

Perhaps the most simple example with which to start is one which in point of fact has been one of the latest to be developed. I showed the first examples of it at a Royal Institution discourse in 1942. In X-ray analysis, it is usual to consider projections of the crystal pattern on certain planes for the sake of simplicity, so breaking down the diffraction problem into a two-dimensional one. It is familiar to workers in this field that the reflexions of X-rays by planes belonging to a zone (parallel to some crystallographic direction) simulate in their intensity the spectra which would be produced if light fell on a cross grating; the pattern of the cross grating is that of the crystal structure projected in a plane perpendicular to the zone axis. If therefore we can make a cross grating with a pattern like that of the crystal when viewed in a given direction, and use it to diffract monochromatic light, we should see a pattern of spectra which are bright or dim in accord-

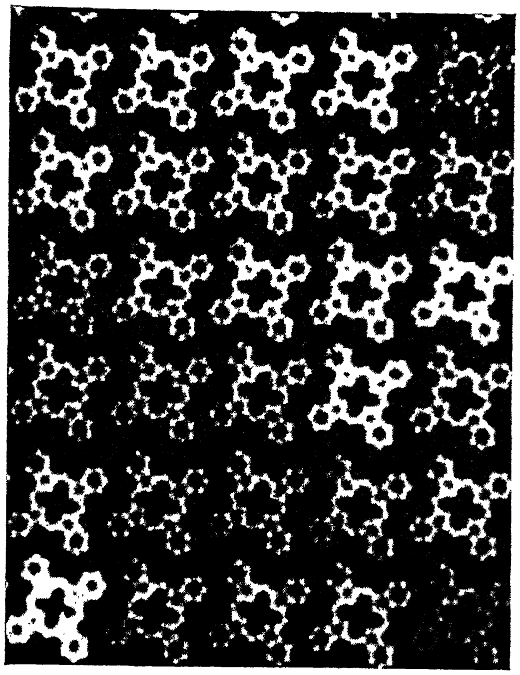

Fig. 1. Microphotograph of cross grating produced by the 'fly's eye'. (Bunn.)

ance with the corresponding X-ray spectra; for example, an array of spots corresponding to all the $hk0$ reflexions if the zone is the $c$ axis.

It would be possible to draw the crystal pattern on a large scale, and photograph it down so as to make a cross grating; but this would be tedious. The 'fly's eye' device makes the construction of the grating a simple matter. A master plate is prepared which consists of a pattern of minute transparent holes 0·04 mm. in diameter in an opaque background. The plate is the negative of a large-scale pattern of

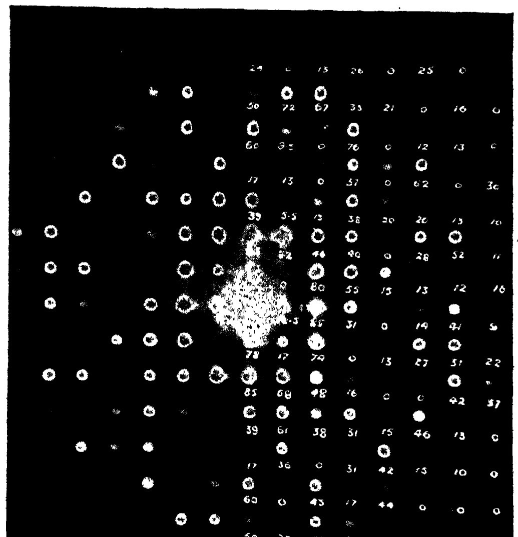

Fig. 2. Cross grating spectra given by the grating shown in Fig. 1. (Bunn.)

* Friday evening discourse at the Royal Institution on March 24.

Fig. 3.

black spots which is photographed down. The holes are spaced about 40 to the centimetre each way. The master plate is laid on a photographic plate with small distance pieces which keep the two surfaces 1 mm. apart. The plate is exposed to a single unit of the crystal pattern, represented by a cluster of lamps at a distance of about one metre; each hole in the master plate throws a pinhole image of the array on the photographic plate, so that the pattern is repeated for every hole. The plate is developed and used as a cross grating. A convenient method is to focus a telescope on a pinhole source of monochromatic light, and place the cross grating in front of the objective.

The method has been greatly improved by Bunn, working in the research laboratory of Imperial Chemical Industries, Ltd., at Northwich. Fig. 1 shows a microphotograph of a cross grating produced by the 'fly's eye'. The units represent the phthalocyanine molecule as determined by Robertson. Fig. 2 shows the cross grating spectra given by the grating, and the numbers represent the strength of the observed X-ray spectra. It will be seen that the correspondence is quite encouraging. The holes in the master plate were in this case at the corners of squares, whereas the unit cell of the crystal projection had no such simple symmetry. However, provided the atoms in the pattern unit have the right co-ordinates expressed as fractions of the cell edges, the interference pattern should check with the X-ray results. The grating in this case was made by moving a single lamp to successive positions of the carbon atoms in the structure unit, and taking an exposure for each position. Since the effective atoms are all carbon and nitrogen, they can be taken to be equal in scattering power. Some research will be necessary to reproduce a pattern of atoms of different kinds in a correct quantitative way, but trial and error will no doubt enable one to arrive at a set of empirical rules which lead to the right quantitative results.

The procedure for crystal analysis is thus as follows. Any proposed structure which is to be tested is drawn to scale, and a lamp placed at each atom in turn. If a number of variants are tried, a series of corresponding cross gratings can easily be photographed side by side on the same plate since each is less than 1 cm. square. By viewing a pinpoint light through them, one can see immediately if any one of them is near the truth.

## The Molecular Scattering Factor

The strength of each diffracted beam in a cross grating pattern is determined by the amount scattered by the unit of pattern in that particular direction. The amount scattered by a single unit is a continuous function of the direction of scattering. In the two-dimensional problem, this function, which is the molecular scattering factor, may be plotted by using contour lines to outline places where it is strong and where it is weak. When the unit is repeated regularly in space, diffracted beams only appear in certain directions (cross grating spectra). If therefore we superimpose on the graph representing the structure factor a grid such that its intersections represent the positions of the spectra, whenever a spectrum falls on a high contour it will be strong and when it falls on a low one it will be weak.

Fig. 3 shows the apparatus for calculating molecular structure factors by using light interference. A pinhole is placed at $F$, at the focus of the lens $A$. Light from a lamp $L$ passing through the pinhole is made parallel by $A$, and passes through a screen $G$ which has a pattern of holes representing the pattern of atoms in the structural unit. A second lens $B$ is identical with $A$, its focus being at $S$. The light waves from the holes in the screen $G$ interfere to build up at $S$ a pattern representing the molecular scattering factor, which can be viewed through the microscope $M$.

Instead, therefore, of building up a complete cross grating as in the 'fly's eye' method, we merely make up a single unit of pattern, representing the atoms by holes in the screen at $G$. A photograph is taken of

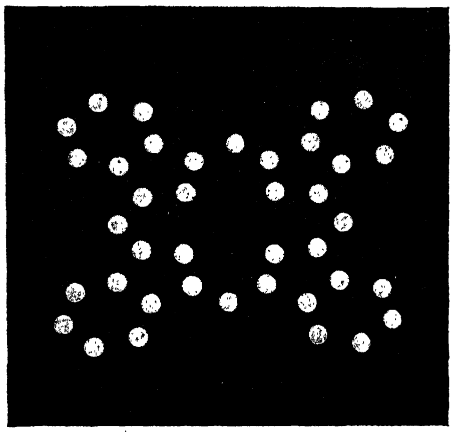

FIG. 4 (a).

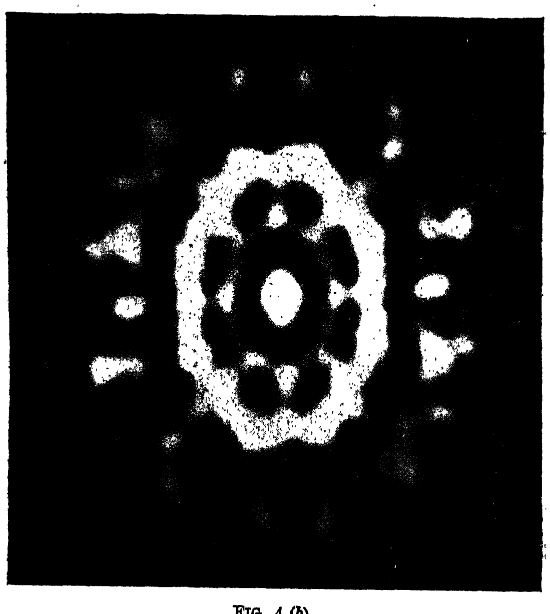

FIG. 4 (b).

Fig. 4. (a) PHTHALOCYANINE MOLECULE. (b) MOLECULAR SCATTERING FACTOR. (FOR COMPARISON WITH (a) REVERSE RIGHT TO LEFT.)

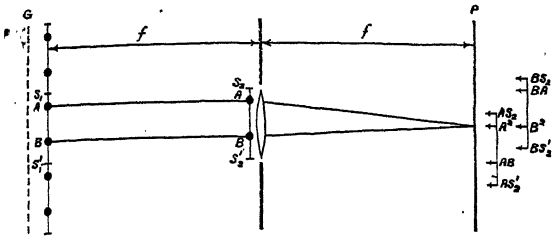

Fig. 5. THE CONSTRUCTION OF A PATTERSON DIAGRAM BY ROBERTSON'S METHOD.

the consequent diffraction pattern at $S$. This is enlarged, and covered by a grid to the right scale which defines the positions of the cross grating spectra. A comparison is now made with a diagram setting out the strength of the observed X-ray beams, plotted to the same scale. If strong and weak X-ray beams correspond to points on the grid where the diffraction pattern is strong and weak respectively, the right pattern unit has been found. Fig. 4*b* shows the molecular scattering factor of the phthalocyanine unit represented in Fig. 4*a*. The fringe pattern before enlargement is about 2 mm. in diameter.

## Patterson Synthesis

The 'Patterson' or 'Vector' diagram is much used in X-ray analysis. We may consider the projection of a crystal on a given plane for the sake of simplicity, though the principle is the same in three dimensions. The electric density of the unit of pattern, projected on a plane, can be represented by a set of contour lines like those on a map which give heights. Such diagrams will be familiar to anyone who has followed the later developments of X-ray analysis. They give the density $\rho(x,y)$ at any point $x,y$ in the unit cell. The Patterson diagram is more complex. It is a plot of a function $P(x_0,y_0)$ which at the point $x_0y_0$ has the value of the double integral taken over the unit cell.

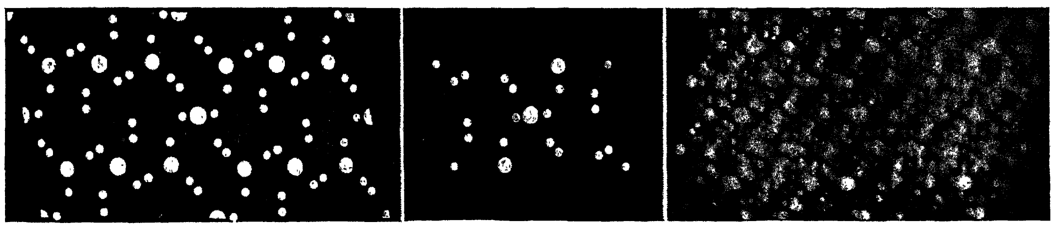
$$\iint \rho(x,y).\,\rho(x + x_0,\, y + y_0)dxdy.$$

It is called a vector diagram because its peaks represent vector relationships between the atoms in the pattern unit. If there is an atom at $x'y'$, and another at $x' + x_0$, $y' + y_0$, the densities will be large around both these points, and so the integral will have a large value around the point $x_0\,y_0$ in the Patterson. Every pair of atoms gives a peak. There is a large peak at the origin, since each atom multiplies itself, so to speak, at this point. The Patterson is complex, because if there are $n$ atoms in the unit cell there are $n^2$ superimposed Patterson peaks, of which $n$ are at the origin. The advantage of the Patterson is that it can be formed directly from the observed X-ray results, in a way indicated in the next paragraph. It often gives a clue to the positions of outstandingly heavy atoms in the structure, or to repeated vector relationships.

Robertson[1] has recently published an ingenious method of constructing the Patterson, given the crystal structure. A variant of his method referred to briefly at the end of his paper is illustrated in Fig. 5. Hägg[2] has suggested a similar method. To get the Patterson, we must (so to speak) multiply the crystal structure by itself.

The atoms in the unit of pattern $S_1S'_1$ are represented by holes in an opaque plate. These appear again at $S_2S'_2$, which is in contact with a long-focus lens. The distances $S_1S_2$, $S_2P$ are equal to the focal length. $S_1S'_1$ is backed with an illuminated sheet of ground glass $G$. The Patterson pattern appears on the screen $P$. The light coming through each hole such as $A$ multiplies the complete pattern at $S_2S'_2$ and throws it on the screen in such a way that $A^2$ appears at the focus $F$, the origin, while $AB$, $AC$, etc., appear in their proper vector relationship to the origin. Similarly, another atom $B$ produces $B^2$ at $F$, whereas $BA$, $BC$, etc., appear in their vector relationship. Fig. 6*a* and *b* show the two screens for the case of $CuSO_4.5H_2O$ projected on the *b* plane, and Fig. 6*c* the resulting Patterson. Alternatively, the lens can be dispensed with by making $S_2S'_2$ on half the scale of $S_1S'_1$.

If therefore the Patterson has been formed from the X-ray results, and we wish to check if a postulated crystal structure gives the same Patterson pattern, we need not calculate the latter. It is sufficient to reproduce the pattern at $S_1$ and $S_2$, and use the arrangement of Fig. 5.



(*a*) (*b*) (*c*)

Fig. 6. (*a*) FIRST SCREEN FOR PATTERSON CONSTRUCTION ($CuSO_4.5H_2O$, *b* PROJECTION). (*b*) SECOND SCREEN FOR PATTERSON CONSTRUCTION. (*c*) THE PATTERSON PATTERN. (FOR COMPARISON WITH (*a*) AND (*b*) REVERSE RIGHT TO LEFT.)

Certain precautions have to be taken. An atom in the pattern unit at $S_2$ which appears at a corner of the cell must be quarter strength, one on an edge half strength, and $S_2$ should be a single unit cell. $S_1$ can be a repeated pattern. In this way the final result at $S$ will have the correct overlapping of peaks of the right strength.

## Building up Fringes

For the sake of completeness reference may be made to the building up of a crystal image by superposition of fringes, though it will not be described here as it has been published elsewhere[3]. Referring to Fig. 3, if two small holes are made in the screen at $G$, a series of fringes will appear at $S$. The amplitude of the fringes is determined by the size of the holes, their orientation is at right angles to the line joining the holes, and their spacing is inversely proportional to the distance between the holes. We can therefore superimpose at $S$ any series of fringes by making the corresponding holes in $G$. The only

variable not conveniently at our command is their phase. Now the Patterson of a crystal can be built up by superimposing elements of a Fourier series, all of which are in phase at the origin or cell corners. The elements of the series are proportional to the measured X-ray intensities. If therefore holes are drilled in the screen $G$ to represent, as cross grating spectra, the intensities of the observed X-ray spectra, the result at $F$ is the Patterson diagram which light has calculated for us from the X-ray results. An example is given in the second article quoted above.

These methods of calculation are as yet in their initial stages, and much remains to be done to perfect them. The success already obtained, in particular with the 'fly's eye' method, is, however, quite promising and they may well prove to be a useful additional weapon in the X-ray analyst's armoury.

# WEST AFRICAN AGRICULTURE

By SIR GEOFFREY EVANS, C.I.E.
Royal Botanic Gardens, Kew

IN the spring of 1938 the Trustees of the Leverhulme Trust invited four members of Parliament to visit West Africa and report upon conditions in the West African Colonies generally. The terms of reference included a study of the standard of life of the native population, the production of food and other materials and in particular certain problems in respect of the development of agriculture, pastoral work and forestry. The investigations considered the problem of the improvement of farming methods and the introduction of new crops; the study of export crops, forestry and animal husbandry and the general problem of soil conditions, including erosion and improvement by better methods of cultivation. Lastly, the existing systems of land tenure were examined with the view of ascertaining whether modifications would be likely to be advantageous in the fullest development of the land. These objects were distinct from the more political aspects of the work of the Commission, and for the purpose of the inquiry certain technical experts were attached. The Technical Reports of the Commission have now been published; that on crop production and soil fertility is a valuable and informative document*. The Commissioners in their foreword to the Report lay down a principle—with which all who have acquaintance with these territories will agree—that any future economic development must be based on the fundamental importance of farming as the major interest of the African people. In view of this the Leverhulme Trust was fortunate in securing the services of such eminent men of science as Mr. H. C. Sampson, with his unrivalled knowledge of agricultural problems in India and East Africa; and Dr. E. M. Crowther, head of the Chemistry Department of Rothamsted, who is an acknowledged authority on tropical soil problems.

The outbreak of hostilities delayed the publication of this Report, and in the meantime the impact of war during the last five years has had the effect of changing conditions in West Africa as in other parts of the world. Nevertheless, the Report gives a faithful and very detailed account of agricultural conditions in the West African Colonies, and the facts related, together with the general conclusions reached, are as true to-day as they were before the War, for certain of the fundamental problems involved cannot be settled in a few years, but will only be resolved as the result of a well-planned and carefully thought out policy applied over a number of years.

The need for organizing research and survey on a much larger scale is stressed with the objective of working out an ecological interpretation of the country and its mode of life. That such surveys are needed is generally conceded, but progress in this direction has been hampered by lack of trained staff. The most striking piece of work hitherto has been achieved in the extreme north of the Northern Territories of the Gold Coast. Here a detailed ecological survey of the thickly populated strip of country comprising the granitic soils of the Dagombo peoples has been followed by the application of a definite system of improved agricultural methods. Elsewhere this principle has been adopted in a more piecemeal manner, but it may be said that in all cases where definite progress has been made, it has always followed the preliminary study of native methods of cultivation and has usually resulted in the grafting of the improved methods on to the native systems rather than the introduction of completely novel methods.

The section on geology and soils forms a valuable addition to our knowledge, and it is worth the study of all officers, administrative as well as agricultural, for the improvement, and, in the final instance, the saving of the soil, is the basis of all agricultural prosperity. The interesting suggestion is put forward that many of the traditional agricultural practices are to be explained in terms of the mineral nutrients necessary for plant life. Generally speaking, it may be said that West African soils are not particularly fertile, and indeed in large areas they are definitely poor. Organic matter decomposes much more rapidly in the tropics than it does in temperate climates, and many of the soils in the dry tropics are short of humus. Most of the surface soils in the wet zone are very deficient in bases and notably lime, phosphates, and potash; an exception being the rich volcanic country around the Cameroon Mountain.

The general shortage of lime is evident in many ways. Thus the native cattle and wild animals are smaller in the wet areas, where the lime and other minerals are readily leached out of the soil by the heavy rain, than in the dryer zones to the north. In the forest areas where cattle can with difficulty live owing to the attentions of the tsetse fly, the application of farmyard manure is not practicable, and experiments are now being conducted by the Agricultural Departments in Nigeria, in particular, to try to replenish the surface soils by means of the residues of certain deep-rooted shrubs which it is believed will draw these mineral nutrients from the subsoil. There are large areas in the country east of the Niger where the soil is so poor that it is impossible to establish a leguminous cover crop, and it is presumed that this is due to the lack of essential minerals. The present custom of cutting and burning the bush, growing a couple of crops and then allowing the land to recover by reverting to bush for a long series of

* The West Africa Commission, 1938–39. Technical Reports. 1. Crop Production and Soil Fertility. By H. C. Sampson and Dr. E. M. Crowther. (London: Leverhulme Trust.)

years, although destructive to timber supplies, was fairly effective so long as there was a sparse population. But in the Ibo country east of the Niger, the population is increasing rapidly and already in some districts it is 1,200 to the square mile. Here the resting period has perforce had to be reduced to two or even one year, so that this land has no time to recover and is rapidly deteriorating. There is no doubt that the evolution of a permanent system of husbandry in the wet forest area is one of the most pressing problems and also one of the most difficult to solve. It is a matter requiring careful and continuous investigation over a series of years. It is believed that these deep-rooted species, such as the rosaceous shrub *Acioa barteri*, bring up nutrients from the subsoil, but there seems to be no definite knowledge with regard to the extent to which this occurs, and detailed information would be advantageous. A central research station to deal with these problems of cultivation in the Forest Belt is badly needed, since a solution is probably the most urgent of all tropical agricultural problems at present.

In the drier parts of the country where it is possible to keep livestock, considerable progress has been made in establishing systems of mixed farming, whereby farmyard manure becomes available for the replenishment of the soil.

Somewhat remarkable results have been obtained by the application of dressings of one or two tons an acre. Such light applications would be considered homœopathic in Great Britain, and an interesting theory is put forward that the increase in yield may be due, in the main, to the minerals and not so much to the humic content of the manure. Further trials with mineral fertilizers are advocated. Phosphates in particular appear to be short, and it is pointed out that whereas rock phosphates may give good results in the acid soils of the Forest Belt, the more soluble fertilizers such as superphosphate may give better results in the neutral soils of the north. The argument that the peasant is so poor and so conservative that he will never readily take to artificial fertilizers is really unsound. In India the *ryot*, who was always considered one of the most conservative of beings, now uses large quantities, but he had to be converted to the value of the practice by prolonged and visual demonstrations. It must also be remembered that large numbers of African peasants have joined the Armed Forces during the last four years and have gained a measure of education and a widening of outlook which will undoubtedly have a big effect on village life when they return after demobilization. All these men will have travelled a good deal and will have learnt a lot from their contact with other peoples and other countries. Most of them have learnt to think for themselves, and will be quicker to take up any new method which promises to be advantageous.

As has already been mentioned, the African soils are deficient in certain important plant foods. The discovery of good deposits of agricultural lime or a reef of good phosphatic rock would be of untold benefit. There are phosphatic rocks in the Yoruba country, but there is no factory for making superphosphates. As it is at present, the country is losing most of its minerals through the export crops such as oil seeds and cacao. The north is also losing vast quantities in the shape of its cattle and animal products. If means could be found to slaughter the cattle in the north instead of sending them down to the coast on the hoof, the bones, horns and other residues could be retained and worked up into superphosphates, dried blood and other fertilizers, and the minerals would find their way back to the land where they came from. As it is at present, the drain from the land each year, in the shape of ground-nuts exported to the coast, is very considerable.

On the subject of erosion the authors very rightly stress the need for urgent action. Soil erosion is evident everywhere to a greater or less degree, and is particularly severe in the Protectorate of Sierra Leone, where the burning of steep slopes for the cultivation of hill rice is causing a rapid loss of soil and the impoverishment of whole areas. In the Ibo country of south-east Nigeria erosion in its most spectacular form is seen, particularly in the Awka division. Here the soils are a light sand, and enormous chasms several hundred feet deep and miles long have been formed. These are extending rapidly and encroaching on the agricultural land, which is already overburdened with a heavy population. Many of these areas are already gone beyond hope of reclaiming, and the best that can be done is to proclaim them forest reserves and get them covered with some sort of tree growth as quickly as possible. The real problem is to prevent further erosion by tackling incipient gulleying at the source and preventing sheet erosion by contouring, strip cultivation and bunding in the fields that are in cultivation. The problem is an administrative one and needs a united drive on the part of the political officers and the local authorities with the technical advice of agricultural and forestry officers. The whole problem involves careful planning, and decisions have to be made with regard to the allocation of certain areas as forest reserves in order to protect the water sheds and to afford shelter belts. The latter are particularly important as a protection against wind erosion in the dryer areas of the north where top soil may be lost by 'blowing', but it is also important in the regions nearer the coast because indiscriminate felling of the forests allows the 'harmattan'—that intensely dry north wind from the Sahara—access to the cacao plantations which require a humid atmosphere for their proper development. Incidentally the belief, current in many quarters, that the fine sand blown by the harmattan is altogether deleterious is not quite correct. It is pointed out that it is not a sand, but is composed of alkaline clay far richer in plant foods than the soils on which it falls, and although only small amounts are deposited each year they are likely to do more good than harm.

It is impossible to refer in detail to the section on crop plants, which are described in some detail, but some reference must be made to cotton and cacao. The former crop is chiefly grown in the Zaria province in Northern Nigeria, and complaints have been made from time to time that the type of American Upland cotton now grown is weak in staple. It is suggested that other species of cotton such as *G. punctatum* or some of the old native cottons might be developed. Shortage of staff and war conditions have prevented action being taken on these lines. Meanwhile, it is worth noting that the Upland cotton, which is an annual crop, seems to produce good strong cotton up to the advent of the harmattan winds in January. When these winds set in the cotton plants suddenly dry up and wilt, and any cotton picked afterwards tends to ripen prematurely and to be very weak in staple. It would seem desirable, therefore, to gin and bale this later picking separately from the main crop, which is picked before the coming of the harmattan.

With regard to cacao, much has happened since this Report was written. It is a remarkable fact that cacao plantations all over the world are now suffering much damage from diseases and pests. The effect seems to become cumulative as the crop reaches about thirty years. During the last five years officers working in the Research Station at Tafo, which was opened in 1937, have discovered that much of the damage that was formerly ascribed to die-back or physiological trouble is in reality caused by a virus or a virus complex, one symptom of which is the 'swollen shoot'. These viruses, together with the attack of capsid bugs, is menacing the whole future of the cacao crop, which is the prop and stay of the Gold Coast. The cacao has shown signs of trouble for years past; but it is only as recently as 1937 that research was contemplated. Now that the danger is apparent, the step recently taken to convert the Tafo Station into a Central Cacao Research Station to serve the whole of West Africa is a great step forward. The Station can now hope to be adequately staffed and equipped, and continuity in the research work will be assured, which was not always the case under the former conditions.

The sections dealing with the types of West African agriculture give a most interesting and accurate account of the methods and will repay careful study.

As regards plantation agriculture, it is pointed out that the present systems of land tenure and Government policy tend to hinder European plantations in our West African Colonies, though this is not the case in adjoining French territories or in the Belgian Congo. So far as the production of crops for export is concerned the plantation system has undoubtedly many advantages over production by large numbers of small individual farmers. It must be remembered that most of these tropical export crops have to be processed in some form or another before they can be marketed. The plantation with its central factory and assured supply of raw material can do this more efficiently and turn out a better product than the small individual. Arrangements can also be made to plant only the best varieties and to effect improvements in planting methods. It is also in a better position to meet the demands of the markets as regards quality, grade and so on, and has a big advantage in the arrangements concerning transport and sale. It was for these reasons that the plantation products of the Far East were rapidly ousting similar products from the West Coast in the period before the War. It would seem necessary to realize that some sort of central organization will be essential in the future and methods need to be worked out whereby the plantations can be organized on a co-operative or collective basis. By this means crops would be raised by individuals retaining many of their old rights and growing their own food crops, but collected round a central factory which would do the processing and arrange for the marketing and transport. A suitable site for such an experiment would be in the British Cameroons. Here agriculture is already based on the plantation system and these plantations, which were formerly enemy property, are being managed temporarily by Government. The soils are extremely fertile and other conditions favourable, and the experiment would be well worth making.

The Report is in every way an informative one and is illustrated by a series of excellent photographs which give a good idea of the lives and occupations of the various races that live in the British West African Colonies.

# EDUCATION IN PREVENTIVE MEDICINE

By SIR ARTHUR MACNALTY, K.C.B.

IN exploring a fresh field of knowledge in any subject, the pioneers have all the fun of the game. They devise their own methods and rules for investigation and try them out experimentally. It is necessary at length, when results have been achieved, to hand on the torch to others, and eventually an educational system, with professorial chairs, lecturers, text-books, demonstrations and the whole gamut of didactic instruction makes its appearance.

The preventability of disease had its ordered beginnings in the eighteenth and early part of the nineteenth centuries, and British practitioners of medicine took the lead of the world in this study. Richard Mead, in 1720, published his "Short Discourse concerning Pestilential Contagion and the Methods to be Used to Prevent it". John Pringle began hygienic reform for the British Army, and Dr. James Lind prevented scurvy and typhus. Other pioneers in preventive medicine were George Baker, Gilbert Blane, Edward Jenner and Turner Thackrah.

These men were all clinicians; they saw the consequences of disease, were not content with alleviating or curing maladies, but sought out their causes. In many cases they discovered that their patients' ill-health was due to bad environmental conditions—poverty, overcrowded dwellings, lack of fresh air and ventilation, filth, dirt and defective sanitation. Clinical medicine produced preventive medicine and constitutes its backbone. By a natural process of events, this new knowledge led to sanitary legislation, to a public health service and to systematic education in preventive medicine.

In an interesting inaugural lecture at the London School of Hygiene and Tropical Medicine, Prof. J. M. Mackintosh has traced the history of this education and foreshadowed its future trends.

It began in the year 1786 with Johann Peter Frank, who held the chair of clinical medicine in the University of Pavia and was appointed director of public health of Austrian Lombardy. In 1789 Andrew Duncan became professor of the Institutes of Medicine in Edinburgh and from 1795 gave weekly lectures on medical jurisprudence, devoting part of the course to the subject of "Medical Police", in which he dealt with both personal and environmental health, including hospitals and contagious diseases. In 1807 a university chair was created in these subjects with the stipend of £100 a year. At this time a number of British teachers were lecturing privately on hygiene, and books were written on the subject. John Roberton's treatise on "Medical Police" appeared in 1809, and in 1824 Gordon Smith defined the subject as "the application of medical knowledge to man in his social state"—no bad definition of social medicine. It was not until the year 1898 that the University of Edinburgh again had the distinction of instituting the first whole-time chair of public health.

The brilliant work of Sir John Simon and his colleagues at the Central Health Authority, and the appreciation of the work of those medical officers of health appointed by Liverpool, London and other progressive authorities, led to the obligatory general appointments of such officers by each local authority in 1872. By the Medical Act of 1886 (Section 21)

degrees and diplomas in public health were instituted. This opened the way for post-graduate teaching in public health to registered medical practitioners, and imposed on the General Medical Council the duty of controlling these qualifications and ensuring a proper standard of instruction. The first diploma was instituted by the University of Dublin in 1871, followed by Cambridge in 1875. Other universities and licensing bodies followed, and the Local Government Act of 1888 laid down that a registered degree or diploma in public health, sanitary science or State medicine was an essential qualification for a medical officer of health to a county or district of more than fifty thousand inhabitants. Regulations of the Ministry of Health now extend this requirement to all sanitary districts.

In the development of post-graduate study in public health, Prof. Mackintosh pays merited tributes to Sir Henry Acland, regius professor of medicine at Oxford from 1858 until 1894, Dr. William Stokes and Dr. Edmund Parkes.

H. W. Rumsey's essays on State medicine contributed much to education and practice. It is of interest to note that so early as 1856 he pointed out that the training and preparation of students for medical and sanitary employment was elsewhere acknowledged to be one of the most serious responsibilities of Government. He added: "It is one which no nation has ever neglected without loss to the State and injury to the people".

The seed thus sown has been long in fructifying, but we see some of its results in the University Grants Committee with its subsidies to medical schools, the foundation of schools with Government approbation and assistance, such as the London School of Hygiene and Tropical Medicine and the British Post-Graduate Medical School; and the recent report of the Royal College of Physicians with its suggestion that the cost of all medical education shall be defrayed by the State. Public opinion in Britain moves slowly. It is some ninety years since Rumsey wrote, and the nation is only beginning to realize its full responsibilities for the training and education of medical practitioners and post-graduates in its own vital interests.

The earliest examples of schools of preventive medicine in its broad and modern sense are the School of Hygiene and Public Health at Johns Hopkins University, the University of Toronto School of Hygiene and the London School of Hygiene and Tropical Medicine. All three schools drew much of their inspiration from a report prepared in 1915 by Dr. W. H. Welch and Mr. Wickliffe Rose and presented to the General Education Board of the Rockefeller Foundation. That Foundation in its wide generosity has promoted education in preventive medicine throughout the world and has made these three schools possible and successful. The first of them at Johns Hopkins University has admirably provided for research, intensive study and general instruction, and by its example has promoted the education and interest in preventive and social medicine throughout the United States. Gratitude is due in this respect to the labours of the late Dr. Welch, whose energy and enthusiasm was undiminished by the passage of years. In his planning of the School and its aims he had the advantage of the late Sir Arthur Newsholme's advice, and the latter's acceptance of the first lectureship in 1919 launched the new school under the best possible auspices. Equally the London School was fortunate in having at its helm such experts in preventive medicine as the late Sir Andrew Balfour and his successor, Sir Wilson Jameson.

In the beginning, organized preventive medicine concerned itself principally with environmental hygiene. The medical officer of health was regarded as a sanitary official chiefly occupied with administration and as having little concern with clinical medicine and the problems of disease, except in connexion with infectious fevers. Of late, preventive medicine has enlarged its activities by taking the individual in hand, by promoting facilities and education for keeping him healthy, and by preventing and treating disease in the individual in order to safeguard the community.

There was first the school medical service; then came the new health services for maternity and child welfare, tuberculosis and venereal diseases. The Local Government Act of 1929 placed many hospitals and other institutions under the control of the major health authorities, and the inter-war Housing Acts further increased the medical officer of health's responsibilities.

Prof. Mackintosh evidently realizes that there is much dead wood in public health education which might with advantage be cut away. This criticism applies both to undergraduate and postgraduate teaching. Too much detailed instruction is still given on sewage and refuse disposal and other problems of environmental hygiene concerning which the future medical officer of health only requires a general acquaintance, and the future general practitioner of medicine needs still less knowledge. The old syllabuses must be taken in hand and revised in the light of Prof. Mackintosh's counsel. Neither does it seem necessary for the public health student to spend so much time in the study of elaborate bacteriological technique and chemical methods of analysis.

Preventive medicine is not only changing but also advancing, and education in the subject must be adapted to the new discoveries and march of events. We see appreciation of the need for research and investigation in the recent founding of chairs of social medicine at Oxford and Birmingham. "In my view the primary aim of a School or University Department of Hygiene is to make good general practitioners in health, to send forth keen, competent men and women, with a high sense of their calling and a scientific outlook." Thus Prof. Mackintosh; and he goes on to emphasize the need in such a school for research in the basic sciences, the application of scientific work to the problems of public health, for example, through surveys, routine laboratory investigations, statistical and epidemiological studies and field experiment, the direct association with current health administration and direct teaching of the principles of preventive medicine. Furthermore, a school of preventive medicine must cater not only for the research student but also for the post-graduate student who desires to pursue intensive study in some special subject, such as statistics or biochemistry. If his bent is towards clinical subjects, for example, tuberculosis or pædiatrics, these are best studied elsewhere under a practising physician.

A course of preventive medicine must be largely academic and must be supplemented afterwards by the holding of clinical appointments to enable the intending medical officer of health to acquire the requisite experience for administrative posts, and to be in a position to appreciate and advise upon the

medical problems which will come before him. Let him beware of sticking too closely to his desk. He must visit clinics and hospitals to refresh his knowledge, be in sympathetic and friendly touch with his medical colleagues, play the man and not the bureaucrat.

These are revolutionary and epoch-making times. Great discoveries are being made in laboratories and hospitals which call for practical application in the prevention of human and social ills. It says much for the promise of the future that, in the midst of a world war, men of vision are able to find time to reflect, as Prof. Mackintosh has done, on the high ideals and humanitarian aims of teaching and practice in preventive medicine, and to plan for the years to come.

# OBITUARIES

## Sir Prafulla Chandra Rây, C.I.E.

BY the death on June 16 of Sir Prafulla Chandra Rây at the ripe age of eighty-three, Indian chemistry has suffered a severe loss. By his own contributions to science, but especially by his personal influence, Sir Prafulla was, more than anyone else, responsible for the great development of scientific research in India during the past fifty years.

P. C. Rây, the son of a small land proprietor, was born on April 20, 1861, and after receiving his early education in a village school he entered the Presidency College, Calcutta, where, although an arts student, he came under the influence of Sir Alexander Pedler, then professor of chemistry in the College, and he thus acquired an interest in chemistry. After graduation he gained a Gilchrist scholarship and in 1882 he proceeded to Edinburgh, where he studied chemistry, physics, botany and zoology. Here, after taking his B.Sc. degree, he worked in Crum Brown's laboratory, for whom he expressed his great admiration and affection. Remaining in Edinburgh for six years, he obtained the degree of D.Sc.; and, on his return to Calcutta in 1888, he was appointed an assistant in the Department of Chemistry at the Presidency College, later succeeding Sir Alexander Pedler in the chair. This appointment he held with great distinction until 1916, when he retired at the age limit and was appointed the first Palit professor of chemistry in the University College of Science. Here he continued to work until 1937, when increasing age and a partial failure of his eyesight compelled him to retire.

Both at the Presidency College and at the University College of Science, Rây built up outstanding schools of research, and nearly all the present professors of chemistry in the Indian universities have worked in his laboratory. Sir Prafulla's great activity over so long a period is all the more remarkable since his health was always poor. He was unmarried and led a very simple life, at one time living in a small room adjacent to the laboratory at the University College of Science. He devoted most of his income to providing stipends for his research students.

Rây's own researches were concerned mainly with the chemistry of the nitrites, and his first notable contribution was his discovery in 1896 of mercurous nitrite. Contrary to the view held previously, he showed that the nitrites are not unstable substances, and in a long series of papers published mainly in the *Journal of the Chemical Society*, he recorded the preparation of ammonium nitrite, the alkylammonium nitrites and various other members of the series. Important as were these investigations, it was by the enthusiasm for research with which he inspired his students that he will best be remembered. He found a further outlet for his energies by founding the Bengal Chemical and Pharmaceutical Works, now one of the leading firms in the Indian chemical industry.

Rây was profoundly interested also in the history of chemistry, and his "History of Hindu Chemistry" will always be regarded as a classical contribution to this field of study. In his later years he devoted much attention to the social and economic problems of India, and in his book "The Life and Experiences of a Bengali Chemist", published in 1933, he gave some account of this side of his activities. Although at times a severe critic of British policy he had a great affection for Great Britain, which he frequently visited. His knowledge of English literature was remarkable, and his tastes catholic, ranging from Shakespeare and Milton to "Tom Jones". He served as a member of a number of Government committees, and his intimate knowledge of India proved of great value in the deliberations of the Indian Chemical Services Committee, of which the late Sir Jocelyn Thorpe was chairman.

Sir Prafulla's services to science did not pass unrecognized; he was made a C.I.E. in 1912 and knighted in 1929. He was a fellow of the Royal Asiatic Society of Bengal and of the National Institute of Sciences, the first president (1924–26) of the Indian Chemical Society and a past president of the Indian Science Congress. His passing will be deeply regretted, not only by his Indian students to whom he was a true *guru*, but also by his many friends in Great Britain.

J. L. SIMONSEN.

## Prof. W. Biltz

ACCORDING to an announcement in the *Chemiker Zeitung* of January 12, Dr. Wilhelm Biltz, professor of inorganic chemistry and director of the Laboratories at the Technical High School, Hanover, died on November 13, 1943. Born at Berlin in 1877, Biltz had a long and successful career as a research chemist and became one of Germany's leading authorities on inorganic chemistry. His work covered a very wide field, for with a succession of collaborators he carried out investigations upon most of the chemical elements, in the course of which he prepared hundreds of new compounds, especially double halides and other double salts, and his work has helped to clarify knowledge of the chemistry of uranium, tungsten, molybdenum and, more recently, rhenium. In his earlier work he gave much attention to density and conductivity determinations of solutions, while later work led him into studies of affinity. This involved heating mixtures of an element and sulphur (or phosphorus, etc.) in varying proportions and submitting the products to X-ray and other methods of analysis (for example, tensimetric) to determine the formulæ of the sulphides, phosphides, etc.

In 1909 Biltz wrote "Laboratory Methods in Inorganic Chemistry", and was for many years joint editor of the *Zeitschrift für anorganische Chemie*, in which many of his papers appeared.

# NEWS and VIEWS

## British Electrical and Allied Industries Research Association

### Retirement of Mr. E. B. Wedmore, C.B.E.

WIDESPREAD regret will be felt throughout the electrical industry that, on account of ill-health, Mr. E. B. Wedmore will be relinquishing the directorship of the British Electrical and Allied Industries Research Association at the end of this year. Mr. Wedmore has been the guiding hand of the Association since its incorporation in 1921 from the Electrical Research Committee of 1918. The success the Association has met with has been due, in no small measure, to his personal efforts, which have always been typified by high administrative ability combined with a wide and thorough knowledge of scientific and practical engineering affairs. The work which has been done by the Association, under Mr. Wedmore's ægis, has embraced a particularly broad field, and in many of the most important branches he has himself been actively concerned. Prior to his association with the E.R.A., Mr. Wedmore's experience included the educational field and the electricity supply industry, and he was prominent as a switchgear designer in the manufacturing industry, being interested very largely in automatic protective systems. His book "Switchgear for Electric Power Control" was published in 1924. He is a member of Council of the Institution of Electrical Engineers, a fellow of the Institute of Physics and has been a notable participant in many national and international conferences and technical assemblies. He was awarded the C.B.E. in 1938.

Mr. Wedmore's non-professional activities reflect the breadth of his interests. He is very well known in bee-keeping circles, and his book, "A Manual of Beekeeping for the English-speaking People", first published in 1932, is regarded as a standard work; bee-keepers throughout the country have long been indebted to him for the great interest he has taken in both the practical and the theoretical sides of their craft. In his own quiet way Mr. Wedmore has done a considerable amount of research work on honey bees and has spent a large part of his spare time lecturing to bee-keepers' associations and doing similar work. He is a member of the Apis Club, and of the Back to the Land Club. For many years Mr. Wedmore has been interested in craniology as applied to character study and in practical aspects of the work of the probation courts. He has also been active in the development of the theory of colour and in the geometry of four dimensions. Mr. Wedmore will take with him the very sincere wishes for a speedy restoration to good health, and a happy retirement, of a large circle of friends in the electrical and associated industries, which include the staff of the Association and the members of the large number of committees through which the Association functions. From January 1 next, Dr. S. Whitehead will take up the duties of acting director of the Association, and from July 1 Mr. R. A. McMahon will become secretary of the Association.

## Astronomy: the Distaff Side

ROBERT S. RICHARDSON has an article with the above title in Leaflet 181 of the Astronomical Society of the Pacific, which shows the important part played by women in the advancement of science. Madame Curie is cited first of all, but most of the examples are taken from astronomy. The writer recalls with amusement the bewildered expression of visitors to the Lick Observatory on some public nights, when, instead of being greeted by an elderly professor, as they expected, they were given a lecture by a young woman. Several examples of the valuable contributions of women to the advancement of astronomy are cited. Madame Jean André Lepaute assisted Clairaut and Lalande in the computations of the perturbations of Halley's Comet by Jupiter and Saturn, and as a result of the work Clairaut was able to announce that the comet would pass perihelion on April 13, 1759. It actually passed perihelion 32 days before the time set by Clairaut; but as Uranus and Neptune were unknown at the time no account was taken of perturbations by these planets. Among other women of distinction reference is made to Caroline Herschel, Lady Huggins and Maria Mitchell, who assisted her father until she was forty-seven with routine computations in connexion with Government surveys for latitude and longitude. She was then appointed professor of astronomy and director of the Observatory at Vassar College, a position which she held until her death. In more recent times we have Miss Annie J. Cannon, Miss Antonia C. Maury and Miss Henrietta S. Leavitt. Not only have women made astronomy their career; they have also acted as patronesses, and notable among these are Mrs. Henry Draper, Miss Helen Snow, Miss Catherine Wolfe Bruce, Mrs. Alexander F. Morrison. Although nearly as many women as men do postgraduate work in astronomy with quite as much success, yet the total number of women engaged in astronomical research is small, because most of them become astronomers' wives instead of astronomers.

## U.S. Committee for Post-War Research for Army and Navy

A COMMITTEE on Post-War Research for the Armed Forces of the United States has been appointed. At the first meeting there were present Charles E. Wilson (*chairman*), vice-chairman of the U.S. War Production Board; Dr. F. B. Jewett, president of the National Academy of Sciences; Dr. J. C. Hunsaker, chairman of the National Advisory Committee for Aeronautics; Dr. K. T. Compton, president of the Massachusetts Institute of Technology; Dr. M. A. Tuve, Carnegie Institute of Technology; Major-General O. P. Echols, assistant chief of Air Staff; Major-General A. W. Waldron, General Staff Corps, chief of Requirements Section, Army Ground Forces; Brig.-General W. F. Tompkins, director of Special Planning Division, War Department General Staff; Colonel R. M. Osborne, Army Services Forces; Admiral E. L. Cochrane, chief of the Bureau of Aeronautics. Other members of the Committee are Brig.-General T. D. Weaver, director of Industrial Demobilisation of the Army Service Forces; Rear Admiral G. F. Hussey, jun., chief of the Bureau of Ordnance, and Rear Admiral D. O. Ramsey, chief of the Bureau of Aeronautics. The purpose of the Committee is to prepare a plan and organizational procedure which will ensure the continued interest of civilian scientific workers after the War, in scientific research for the U.S. Army and Navy.

## Mosquitoes in Britain

THE British Mosquito Control Institute at Hayling Island, Hants, has recently issued at the price of 1*s*. a useful pamphlet entitled "The Morphology and Biology of *Culex molestus*: Observational Notes for Investigators". The object of this publication is to facilitate the investigation of cases in which mosquitoes are causing (or periodically cause) annoyance in dwelling-houses or other buildings, especially those in 'built-up' areas. From among thirty species of mosquito known in Britain, *Culex molestus* closely resembles our commonest mosquito, namely, *C. pipiens*, in many ways. It is, however, a fierce and persistent blood-sucker of man, whereas *Culex pipiens* rarely (if ever) bites human beings. The species *molestus* can lay eggs without having had a blood-meal, although the number of eggs laid is much reduced. It breeds at all times of the year, and mating, unlike that of almost all other mosquitoes, can occur in a very confined space. So far as is known it breeds chiefly in accumulations of water in dark or semi-dark warm situations, but a good deal more needs to be found out on this subject and many other features regarding its habits. So far, *Culex molestus* has only been recognized in London, Harwich and Hull, but it needs to be known whether it has a wider distribution in the country. Anyone willing to help in this investigation can receive a free copy of the pamphlet mentioned on application to the Director of the Institute, Mr. J. F. Marshall, whose temporary address is "Wayside", 47 London Road, Cheltenham.

## Diets for Patients with Ulcers of the Stomach and Duodenum

THE Ministry of Food, in collaboration with the Ministry of Health, has prepared a twelve-page pamphlet of diets for patients with ulcers of the stomach and duodenum. This pamphlet, which is not intended for the general public, since the dieting of cases of the above type is a matter for expert supervision, is approved by the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council and will, it is hoped, help general practitioners, and others professionally concerned with the feeding of such patients, to cope with difficulties of war-time food supplies. The pamphlet contains rules for feeding and planning diets, weekly menus and recipes for patients who have either recovered from the acute stage of peptic ulcer or from whom symptoms due to the ulcer have almost disappeared. In planning the menus, the aim has been to provide a reasonably varied diet based on the foods available under present conditions to these patients. Copies of the pamphlet may be obtained by those professionally concerned with the problem, on application to the Secretary (Public Relations Division), Ministry of Health, Whitehall, S.W.1.

## Incidence of Scarlet Fever

ACCORDING to the *Weekly Epidemiological Record* of March 2, in recent years scarlet fever has ceased to be a disease of any great clinical importance, but its geographical distribution is extraordinary as it is very frequent in northern latitudes and practically unknown in the torrid zone. In the seventies of the nineteenth century, its fatality in northern Europe was more than 10 per cent, and in mortality it exceeded any other acute infection. Between 1875 and 1885 the mortality was halved; it was halved again between 1885 and 1900, and in the present century it has fallen below 1 per cent. Scarlet fever is endemic in all parts of the world in which it occurs, but shows wide variation in incidence from year to year. During the present War, the incidence of this disease has shown no relationship to the public nutrition or the state of military activity, as is shown by the fact that in Germany, which is the best nourished country on the Continent and presents the greatest military activity, the incidence of scarlet fever is excessively high, as it is also in Norway, Holland and Greece, where the nutrition is low. In England and Wales, where the nutrition is good, incidence of the disease fell below normal until 1941, since when it has shown a slight increase. In the United States the numbers are still falling. It is noteworthy that in no country where returns are available has there been any reported increase of severity.

## Substitutes for Structural Material in South Africa

MR. N. Stutterheim and Mr. J. Shaw, of the Investigation Section of the Building Control, South Africa, described some work carried out by the Section during the ten months of its existence at a meeting of the South African Society of Civil Engineers on March 15. They discussed particularly the investigation of substitutes for steel and timber for building purposes. The work is being carried out in the Civil Engineering Department, University of the Witwatersrand, under Prof. Bernard H. Knight, acting head of the Department. The most promising material examined, taking South African conditions of service and also the question of supplies into consideration, appears to be 'Sorel' cement with sawdust filler, reinforced with wood lathes. It can be sawn, nailed and screwed, and tends to expand and contract with varying moisture conditions much as timber does. Its chief economic recommendation is that it can be cast to any size or shape without the use of high temperature, high pressure or skilled labour. Some houses have been built in Johannesburg in which all timber has been replaced with 'Sorel' cement composition. A sawdust cement composition has also been developed by certain South African firms. Other research work carried out by the Investigation Section has been the testing of tiles and flooring materials; for testing the latter, a machine has been devised in the University of the Witwatersrand consisting of leather pads fed with crusher dust to simulate the abrasive effect of leather soles and dust.

## Properties of Paracon

ACCORDING to an article by B. S. Biggs (*Bell Lab. Rec.*, 22, No. 7; March 1944), when the development of 'Paracon', a new synthetic rubber, was announced by the Bell Laboratories, its resistance to oil and heat and its low brittle point, lack of odour and fast curing cycle were emphasized. Not all these characteristics can be held at maximum values in every composition, but various combinations of them can be obtained by selecting the intermediate compounds used in manufacture. This follows because the 'Paracons', in contrast with most elastic compounds, comprise a group of compounds rather than a single one. Chemically, the 'Paracons' are chain esters of high molecular weight. Among the substances that may be used are sebacic and succinic acids and ethylene and propylene glycols. These chemicals are obtainable from agricultural, coal and petroleum

products. Some of them are manufactured in reasonably large quantities, but they are inadequate to produce the huge tonnage of rubber used in the United States. For this reason and also because of its characteristics, 'Paracon' will probably remain a speciality product. The article gives some of the properties and uses of the material.

### *Portugaliae Physica*

A NEW Portuguese journal of physics, *Portugaliæ Physica*—the first of its kind in that country devoted entirely to physics—has been established and has published its first number. The four papers which it contains comprise a calculation of the matrix of electrostatic interaction and orbit-spin for $d^2p$ with an application to the spectrum of Ti II, a mathematical discussion of a group of operators with suggested application to quantum theory, and two papers on $\beta$-ray spectra with reference to internal conversion. In one of these, A. Gibert finds some evidence in support of Stahel's view that the energy quantum can be shared by more than one electron. At a time when the study of pure science has been necessarily replaced for so many by sterner pursuits, it is pleasant to realize that there are still countries where it is growing and needs new mediums for publication. Correspondence relating to the journal should be sent to *Portugaliæ Physica*, Faculdade de Ciências, R. da Escola Politécnica, Lisboa-Portugal.

### Libraries Board of South Australia

THE annual report of the Libraries Board of South Australia, covering the year July 1942–June 1943, refers to the opening on July 30, 1942, of new temporary accommodation for the country lending service, with a further great increase in the number of books issued, as well as to the rapid development of the research service. The latter is now receiving inquiries from every State in Australia for its lists of scientific and technical literature. Through the Scientific Liaison Bureau it is establishing relations between bodies carrying on similar work through the Commonwealth. The Board emphasizes the urgent need for building extension to cover the expansion of the research service, etc. During the year 4,615 books were added, making a total of 197,112 and in addition to 7,500 volumes in the Symon Library and 10,757 in the country lending service. The main library catalogue now contains about 541,648 cards.

### Earthquakes during March 1944

DURING this month eleven strong earthquakes were registered by the seismographs at the observatory at Toledo (Spain). The strongest to be recorded occurred on March 9, when *iPz* registered at 22h. 23m. 24s. from an epicentre some 62·5° distant; the earthquake attained a maximum amplitude at Toledo of 330 $\mu$ at 22h. 47m. 00s. The shock finished recording at 1h. 00m. 00s. on March 10.

At Wellington, New Zealand, during the same month, three strong earthquakes were registered by the instruments. These occurred on March 10, 22 and 31. In addition, eleven local earthquakes were felt in New Zealand during the month. The areas where these were reported as felt were Takaka, Nelson (March 15), Taupo (three times on March 20), Puysegur Point (on March 26), and Milford Sound (on March 29).

The United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, has determined two more provisional epicentres during the month. The earthquakes occurred on March 22 and March 31. The former was recorded at both Toledo and Wellington, and the latter at Toledo. On March 22 the earthquake happened at 0h. 43·0m. G.M.T. and its epicentre, based on instrumental reports from eleven stations, was found to be at lat. 7° S., long. 126° E., which is in the Banda Sea. On March 31 the earthquake occurred at 20h. 34·8m. G.M.T., and on instrumental reports from Fordham, Philadelphia, St. Louis and San Juan the epicentre has been calculated to have been at lat. 3° S., long. 81° W., which is in Ecuador.

### Announcements

PROF. PETER KAPITZA has been awarded the Order of Lenin on the occasion of his fiftieth birthday, in recognition of his outstanding scientific achievements in physics.

PROF. W. P. WYNNE, emeritus professor of chemistry in the University of Sheffield, and a fellow of the Royal Society since 1896, has been elected a fellow of the Imperial College of Science and Technology, which he entered as a student sixty-three years ago.

THE Minister of Food has appointed Mr. Angus McKenzie, teacher of bread-making at the Royal Technical College, Glasgow, as a travelling bread adviser for Scotland. Any baker wishing to avail himself of Mr. McKenzie's services should either write to the Director of Bread, Bryn Euryn, Colwyn Bay, or Mr. McKenzie at his home address, 206 Cambusnethan Street, Wishaw.

AT the annual degree congregation of the University of Birmingham, the honorary degree of D.Sc. was conferred on Ernest Ansley Watson in recognition of his distinguished contributions to electrical engineering and, in particular, of his work on magnetos and on electric lighting of mines. The honorary degree of M.D. was conferred on Dr. Harry Guy Dain, Chairman of Council of the British Medical Association. The honorary degree of Master of Surgery was conferred on William Warwick James, in recognition of his eminent work on maxillo-facial injuries.

IT has been decided to postpone the conference on "The Nutritional Role of the Micro-flora in the Alimentary Tract", which the English Group of the Nutrition Society was to have held on July 22, at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1. An announcement concerning the revised arrangements will be made later.

THE Council of the Royal Society of Arts offers the following awards under the Thomas Gray Memorial Trust, the objects of which are "The Advancement of the Science of Navigation and the Scientific and Educational Interests of the British Mercantile Marine": a prize of £50 to any person of British or allied nationality for an invention, publication, diagram, etc., during the period January 1, 1939–December 31, 1944, which is likely to be of value in navigation; an award of £50 for a deed of professional merit by a member of the British Merchant Navy during the year ending September 30, 1944. Claims in connexion with both awards must reach the Acting Secretary, Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2, before December 31, 1944.

## Terrestrial Nemertines and Planarians in Britain

IN September 1943 I made a search for terrestrial planarians in the woods around the Yealm Estuary, South Devon. While doing so, a number of interesting organisms were brought to light.

(1) A terrestrial nemertine was found in the damper woods under fallen branches and later under stones and wood in damp situations in more open ground. It was commonly in company with the triclad *Rhynchodemus terrestris* and in places was numerous. It was found in widely separated places on both sides of the Estuary. The characters of this nemertine agree with those of *Geonemertes dendyi* Dakin.

The specimens were 5–15 mm. long and in general were of a yellowish colour with two brown longitudinal stripes on each side of the rhynchocoel. But the colour varied from almost white to orange, dark brown or even a purplish pink. The specimens possessed the arrangement of the eyes characteristic of the species, that is, two anterior groups of 4–6 eyes and two posterior groups of 3–5 eyes. The internal characters agree with those given by Hett[1] and Stammer[2]. Details of these will be published later. The only difference to be noted was in the number of proboscis nerves. Stammer gave the characteristic number of these as 14–15. Waterston and Quick[3] describe specimens with 13 proboscis nerves while my specimens commonly have 13 nerves, but sometimes 12 and in one case 11. In all the species of this genus, however, the number of proboscis nerves is variable, and in the two species closely related to *G. dendyi* their number is greater than 14. Of the many interesting anatomical features presented by these worms, the most outstanding is the nephridial system. The existence of this was mentioned by Stammer, but has not been described by him or by others. In my specimens the nephridial system shows the same peculiar characters as those in related species of the genus such as *G. hillii* Hett[4]. There are numerous small protonephridia immediately beneath the weakly muscular body wall. From each group of these a thin-walled duct leads to a long, coiled, glandular canal the cells of which have a very marked radial striation. This canal leads in turn to a duct opening to the exterior. These openings are very numerous. The glandular canals of my specimens are highly developed. They occupy well-defined lacunæ in the parenchyma and form conspicuous objects immediately beneath the muscle layer, particularly above and below the lateral nerve cords. The specimens that have been sectioned all proved to be females, but many were fertile and laid eggs which developed into young in about three weeks.

*G. dendyi* has been recorded three times. It was first described by Dakin[5] from a single specimen from Western Australia. Since in addition those species most closely related to it are confined to Australia, it is probable that the species is itself of Australian origin. Its subsequent history is remarkable. It was next found by Stammer in 1934 in greenhouses in Breslau. In 1937, it was recorded by Waterston and Quick in wild country near Swansea in Wales. It is now found apparently well established at places scattered round the Yealm Estuary in Devon. The possibility that it has been introduced into the northern hemisphere with some Western Australian plant suggests itself. An account of this organism will be published later.

(2) In company with *Rhynchodemus terrestris* were found at widely separated places round the Yealm Estuary a very few specimens of a Rhynchodemus clearly different from any recorded British species. It was some 6–10 mm. in length, of a brownish grey colour with two longitudinal purple brown stripes. Near the anterior end were two highly developed eyes with large lenses. The pointed snout is commonly carried a little upturned, giving the animal a somewhat ludicrous appearance of disdain. The organism is frail, and identification must await the collection of further specimens. In external characters, however, it agrees with Leidy's[6] description of the American species *Rhynchodemus sylvaticus* Leidy.

## Birds and Butterflies

DURING a month's leave in the Anamalai Hills, Cochin State, South India, I have been studying the question of attacks by birds on butterflies. Both place and season (February–March) were well suited to such a study. The hills are covered by rain-forest, holding a rich fauna of insectivorous birds; and when I was there, shortly before the rains, some forty species of butterflies were on the wing, and some of these were common to abundance.

Take first the question of birds attacking butterflies in flight. Of insectivorous birds which take their insect-prey upon the wing, there were present: the large racquet-tailed drongo, bronzed drongo, wood shrike, paradise flycatcher (Tchitrea), several small flycatchers, broad-billed roller, chestnut-headed bee-eater (*M. leschenaulti*), spine-tailed swift, and the common Indian swift. I watched all these regularly, in the open glades, clearings and pathways which were the favourite haunts of butterflies; and I paid particular attention to the drongos, as being large, strong-flying birds, and a conspicuous feature in the jungle. *I did not see a single bird, of any species, catch or chase a butterfly.*

Two aspects of the question seem to me to have been all too little attended to. The first of these is the *time factor*. Jungle birds, like so many others, have their two main times of feeding and activity—early morning and late afternoon. While I was in the jungle, they started feeding about half-past seven and became idle about 10 a.m.; and then got to work again from about 4.30 p.m. until dusk. But the busy time for the butterflies was just the opposite; they were mostly on the wing in the middle of the day, from about 11 o'clock until four. Moreover, the butterflies seldom flew much higher than four

or five yards from the ground; while most of the insectivorous birds, especially the drongos, bee-eaters, rollers and swifts, feed twenty feet up at the least. There may be no hard and fast line here, but there is a clear and general tendency.

It was in these same hills that Mr. Salim Ali recorded[1] a huge hatch of "thousands upon thousands" of the large butterfly *Danais melissa dravidarum*, which were being taken on the wing by the ashy swallow shrike (*Artamus fuscus*). This bird I did not see. But Mr. Salim Ali notes that "*they were the only bird-species interested in these butterflies*", and concludes, from his observations elsewhere, that their food "seems to consist of butterflies to a very large extent".

Attacks by birds on butterflies not flying but at rest is the second part of my subject; and I found a good many more birds taking their insect-prey from trees and undergrowth than hawking it on the wing. Swifts, rollers and bee-eaters took no insects at rest, only those on the wing; all the others mentioned above took them at rest, and so did the other insect-eating birds, such as the babblers, warblers, white-eyes (Zosterops) and orange minivets; while bulbuls, mynahs and tree magpies were all partially insectivorous. It is not so easy to watch the feeding-habits of these birds as of those which take their prey upon the wing; but once again, my results were all completely negative—these birds ate no butterflies at all.

As to the ecological side of the question, most of the butterflies go to rest within small clumps of bamboo and other undergrowth, or occasionally in the inner foliage of evergreen trees. But only a few birds made these their usual feeding-places, such as the warblers and the white-eyes, both small birds with weak bills, and the babblers which are strong active birds; these latter roam the forest in bands or companies, and habitually search the dense thick undergrowth, the resting habitat of many butterflies. Thus the babblers would seem to be by far the most likely predators on butterflies (in addition to Artamus) in this region. But though I caught a number of butterflies, and paid particular attention to those with tattered wings, in no single case could I detect a trace of beak-marks on their wings.

## Production of Mutations by Allyl *Isothiocyanate*

In the course of the past few years, we have examined a number of chemical substances for their ability to produce gene mutations. The experiments were carried out on *Drosophila melanogaster*. Some of the substances were found to be highly effective, producing mutation-rates of the same order as those obtained with X-rays, 6–24 per cent sex-linked lethals developing in treated $X$-chromosomes. These data will be published later.

Although the production of mutations by these potent synthetic substances is of great interest for the light it may throw on the nature of the gene and the process of mutation, the search for naturally occurring substances with the capacity to produce the same effect appears, from the point of view of evolutionary theory, even more important. It is therefore of special interest that among the substances tested we have found one, namely, allyl *iso*thiocyanate (mustard oil), which has a definite though slight effect on the mutation-rate, and which occurs naturally in a variety of plants, for example, *Brassica nigra* and other Cruciferæ (Klein[1]). A summary of the data on which this conclusion is based is given below. A full report will appear later.

The technique used was the *ClB* test for sex-linked lethals, which is the standard test used for detecting lethal mutations which develop in the $X$-chromosomes of the spermatozoa in treated (and control) males. Two experiments were carried out. With the second a control was done simultaneously on flies collected from the same culture bottles as the flies for treatment. The results are shown in the accompanying table.

| Expt. | No. of $X$-chromosomes tested | No. of lethals detected in the chromosomes | Lethals (per cent) |
|---|---|---|---|
| 1 | 756 | 17 (+1 doubtful) | 2·2 |
| 2 | 878 | 19 | 2·2 } Diff. = 15 ± 4·8 |
| Control | 963 | 4 | 0·4 } |

The difference between the treated and control series in the second experiment is clearly significant. Moreover, in both experiments the mutation-rate markedly exceeds the range of the spontaneous occurrence of sex-linked lethals in normal stocks, which scarcely ever reaches even 1 per cent.

In addition, three sex-linked visible mutations were obtained in the two treated series, none in the controls.

Experiments are under way to determine whether allyl *iso*thiocyanate can also produce chromosome breaks.

## Increased Alkaloidal Contents of Induced Polyploids of Datura

TETRAPLOID plants of various species of Atropa, Datura and Hyoscyamus have been produced by the treatment of their seeds with colchicine solution; polyploidy being judged by the sizes of stomata or of pollen grains and by chromosome counts in root-tip preparations. Tetraploid plants of *Datura Stramonium* Linn. and *D. tatula* Linn. were healthy in appearance and produced as great a weight of dry leaf per plant as the diploid controls. Abundant viable seed was collected from them and produced $F_1$ and $F_2$ generations of tetraploids in the two following years.

Chemical determinations of the individual alkaloids *l*-hyoscyamine, atropine and hyoscine have been carried out on the dried leaves from diploid and tetraploid plants grown from seed of different origins. Results of assays, calculated with reference to the leaves dried at 100° C. for six hours, are shown in the accompanying table.

Analyses of $F_1$ and $F_2$ generations showed similar

| Seed stock | Diploid controls | | | | Tetraploid plants | | | |
|---|---|---|---|---|---|---|---|---|
| | Total alkaloid per cent | Percentage ratio of total alkaloid | | | Total alkaloid per cent | Percentage ratio of total alkaloid | | |
| | | Hyoscyamine | Atropine | Hyoscine | | Hyoscyamine | Atropine | Hyoscine |
| *Datura Stramonium* | | | | | | | | |
| A | 0·20 | 81 | 5 | 14 | 0·55 | 82 | 6 | 12 |
| B | 0·35 | 68 | 18 | 14 | 0·50 | 78 | 8 | 14 |
| C | 0·27 | 76 | 8 | 16 | 0·50 | 75 | 12 | 13 |
| *Datura tatula* | | | | | | | | |
| A | 0·24 | 83 | nil | 17 | 0·40 | 85 | nil | 15 |

alkaloidal contents to those of the parental tetraploid plants. The provisional conclusion may thus be drawn that the percentage total alkaloidal contents of tetraploid plants of *D. Stramonium* and *D. tatula* are approximately double those of the diploid plants; while the proportions of the individual alkaloids present remain unchanged.

Assays of tetraploid and diploid material from other species of Datura and from species of Atropa and Hyoscyamus are not yet completed. It is hoped to publish a detailed account of these researches when the results of the 1944 growing season have been obtained.

## Relation of the Concentration of Vitamin A, Carotenoids and Cholesterol in Milk Fat to the Size of the Fat Globules

SOME time ago, Henry *et al.*[1], in measuring the vitamin A and carotene content of samples of fat churned or extracted by solvents from the same batch of milk, found that the concentration of vitamin A was the same in the fats prepared by both methods, but that there was slightly more carotene in the extracted fat. This they attributed to destruction during churning.

We have now obtained substantial evidence to show that this explanation is not correct, and that the small difference was due to the relatively high concentration of carotenoids in that fraction of the original milk fat which remained in the separated milk. We have carried out several experiments in which vitamin A and carotenoids were measured at the different stages of butter-making. In some of these experiments cheese was also prepared from the same bulk of milk and similar measurements were made on the whey, and at the different stages of butter-making from whey. Samples obtained during the separation by gravity of cream from milk were also examined. The results quoted in the accompanying table may be taken as an example. It shows that although the vitamin A was substantially the same in all fractions, the fat of separated milk contained seven times and the fat of separated whey eleven times as much carotenoids as the original milk fat. These two fractions consisted of the smallest fat globules which were not removed by two centrifugings in a dairy separator. The concentration of carotenoids in the fat of buttermilk and in the fat of whey was also higher than in the original milk, though the difference was very much less marked. Measurements showed that the size of the fat globules of these fractions was intermediate between that of the globules of the original milk and that of the separated milk. It will be seen that a very close correlation exists between the amounts of carotenoids and of cholesterol in the various fat fractions. Our values for cholesterol are of the same order as those reported by Frengley and Herrick[3] and by Ansbacher and Supplee[4] in similar fractionation experiments. Iodine values of the fatty acids prepared from the fats varied little, but were somewhat higher in the fats from separated milk and separated whey.

The difference in behaviour between vitamin A and carotenoids is very striking. The uniform concentration in which the former occurs in the different fat fractions suggests that it may be in true solution in the fat. The carotenoids and cholesterol, on the other hand, are present in greater amounts in those fractions in which the ratio of fat globule surface to fat is higher, and therefore may be associated in some way with the fat globule membrane.

Further work on these problems is in progress.

| Fraction | Method of extraction of fat | Fat (gm. per 100 ml.) | Vitamin A (I.U. per gm. fat) | Carotenoids (μgm. per gm. fat)** | Cholesterol (mgm. per gm. fat) | Iodine value of fatty acids | Average radius of fat globules (mean of 200 measurements) |
|---|---|---|---|---|---|---|---|
| Milk | Solvent* | 3·14 | 24·7 | 9·8 | 3·3 | 38·5 | 1·41 |
| Cream | Solvent* | 35·35 | 25·3 | 9·5 | 2·8 | 41·5 | 1·68 |
| Separated milk | Solvent* | 0·06 | 21·6 | 65·4 | 36·0 | 45·2 | 0·51‡ |
| Butter | Churning | 86·90† | 26·3 | 9·4 | 2·5 | 40·2 | — |
| Buttermilk | Solvent* | 1·98 | 24·2 | 12·2 | 6·0 | 42·3 | 0·89 |
| Whey | Solvent* | 0·42 | 23·2 | 14·9 | 5·6 | 37·8 | 1·09 |
| Whey cream | Solvent* | 18·20 | 24·7 | 9·4 | 3·3 | 40·2 | 1·80 |
| Separated whey | Solvent* | 0·03 | 26·2 | 111·0 | 46·0 | 48·0 | § |
| Whey butter | Churning | 83·90† | 26·3 | 9·3 | 2·7 | 40·1 | — |
| Whey buttermilk | Solvent* | 2·25 | 23·9 | 12·4 | 5·3 | 42·0 | 0·84 |

* The method was that of Olson *et al.*[2] slightly modified.
† gm. per 100 gm.
** The percentage of β carotene measured by chromatography did not vary greatly in the different fat fractions; the range was 74–82 per cent.
‡ Only 50 globules measured.
§ Owing to small size and scarcity of the fat globules, satisfactory measurement was not possible.

## Production of Penicillin

THE usual method adopted in the large-scale production of penicillin is to grow *Penicillium notatum* on shallow layers of modified Czapek-Dox media[1] at 24°C. for 10–12 days. The metabolic solution at the end of the incubation period has an activity of 3–4 'Oxford' units per c.c. This process involves handling large volumes of solution, and the space required is enormous. Moreover, the danger of contamination by penicillin-destroying bacteria during the lengthy incubation period is obvious.

Various attempts to shorten the incubation period and increase the yield of penicillin have been made; the more important ones are by Clifton[2] and by Srinivasa Rao and De[3]. The first one suffers from the difficulty of bacterial contamination. The second method using semi-solid media has been developed further in our laboratories.

Among the various semi-solid media tried by us, the best so far was found to be wheat bran. It provides the necessary loose physical structure facilitating aeration and also provides a large surface for growth of the mould. Maximum anti-*Staphylococcus aureus* activity was reached after 48 hours incubation. Addition of nutrients like yeast extract, etc., did not increase the yield of penicillin or shorten the incubation period. The procedure is briefly as follows:

30 gm. of wheat bran (particles of large size are preferable) are weighed out into 750 c.c. conical flasks, moistened with equal weight of water and mixed well. The flasks are plugged and autoclaved at 15 lb. pressure for one hour. The sterilized flasks are then inoculated with about 1 c.c. of a spore suspension of *Penicillium notatum*, well shaken and incubated at 24° C. for two days. The flasks are shaken once after 24 hours. This procedure gave consistently penicillin activity of 30 'Oxford' units per gram with Fleming's strain (N.C.T.C. No. 4222) tested by serial dilution method against *Staphylococcus aureus* Oxford. Another strain of *Penicillium notatum* has given us an activity of 150 units per gram.

The advantages claimed for the above process apart from low cost of manufacture are: (1) ease of handling semi-solid media; (2) consistent yields; (3) growth-time is reduced to two days, which is equivalent to increasing yield by five or six times; (4) the water extract of mouldy bran can be concentrated by using it for re-extraction with fresh mouldy bran to a fairly high potency; (5) bacterial destruction of penicillin is avoided; (6) large-scale methods used in the manufacture of taka-diastase can be used.

The concentrated crude extract is being used for local application to surface wounds with very good results.

My thanks are due to Drs. S. P. De and N. H. De for kind assistance and to Prof. V. Subrahmanyan for his keen interest in the work.

## Production of Ovulation by Fluoride *in vitro*

IN the course of an investigation on the action of enzyme inhibitors on pituitary-induced ovulation of the frog's ovary (*Rana pipiens*) *in vitro*, it was found that sodium fluoride would potentiate the pituitary effect. This unexpected result was considered as possibly associated with the binding of calcium by fluoride. Accordingly, the effect of other experimental procedures such as the use of calcium-free Ringer, oxalate, change in *p*H, etc., was investigated. A summary of the results together with probability values is shown in the accompanying table.

| Agent | Molar conc. | Pairs of ovaries | No. eggs extruded | | Value of *P* |
|---|---|---|---|---|---|
| | | | Treated | Control | |
| Sodium fluoride with pituitary | $10^{-2}$ | 4 | 2159 | 634 | $<0.01$ |
| Sodium fluoride without pituitary in calcium-free Ringer | $10^{-2}$ | 16 | 1699 | 1 | $<0.01$ |
| Sodium oxalate | $10^{-2}$ | 12 | 3630 | 3974 | $<0.05$ |
| Calcium-free Ringer | — | 8 | 1822 | 1031 | 0·05–0·01 |
| Ringer *p*H 5·6 (treated) and *p*H 7·4 (control) | — | 8 | 672 | 2593 | $<0.01$ |
| Sodium iodoacetate | $10^{-[illegible]}$ | 4 | 0 | 1766 | 0·05 |
| Sodium iodoacetate | $9\times10^{-5}$ | 4 | 395 | 1366 | 0·05—0·01 |

The procedures were similar to those previously reported[1]. Unless otherwise specified, the ovaries were removed and suspended in a total volume of 30 c.c. of buffered Ringer (*p*H 7·4) containing female frog pituitary together with the agent to be tested. Ovaries were studied in pairs, the left ovary serving as control for the right and vice versa. The total number of pituitary glands for the experiment was removed, finely macerated in 1–2 c.c. of distilled water, and taken up in a large volume of Ringer. The equivalent of two pituitary glands was then pipeted into a Petri dish into which one ovary was placed. Each experiment was allowed to run 31 hours, at the end of which time the ovaries were washed and the extruded eggs counted.

It is apparent (see table) that sodium fluoride potentiates the effect of pituitary in inducing ovulation and will, moreover, by itself cause egg release.

Fluoride may be considered to exert its action either through (1) a binding of calcium, or (2) an inhibition of some portion of the respiratory or glycolytic mechanisms. Chambers[2] found that calcium is necessary for the stability of the intercellular cement of capillaries and kidney tubules; and when the calcium of the cement substance is decreased by using calcium-free solutions or lowering the *p*H, it becomes loosened. Loosening of the intercellular cement could be expected to favour ovulation by permitting a more ready rupture of the cell layers surrounding the egg. While the results with fluoride and calcium-free Ringer might be interpreted on this basis, the oxalate and *p*H experiments apparently do not support such a view.

With respect to the action of fluoride on glycolysis, one may postulate that the accumulation or deficiency of a particular intermediate substance or substances initiates processes which result in ovulation. The relatively high concentration of fluoride ($10^{-2}$ *M*) may well inhibit respiration as well as glycolysis. Inhibition

of the glycolytic mechanism as a whole, however, does not satisfactorily explain the fluoride effect, inasmuch as iodoacetate, which produces the opposite effect to fluoride on ovulation, also inhibits glycolysis[3]. Oxalate, which is without significant effect on ovulation, may also inhibit glycolysis under certain conditions, but is without effect on living yeast, presumably because of its failure to penetrate[4].

We have been obliged to discontinue these experiments temporarily owing to the advent of the season of spontaneous ovulation in our frogs.

Grants in aid of this work received from Eli Lilly and Co. and the National Research Council of Canada are gratefully acknowledged.

## Treatment of Blackwater Fever

HÆMOLYTIC substances were demonstrated in the peripheral blood of three patients. They appear a few minutes before an attack of hæmoglobinæmia and are rapidly removed from the serum by the red blood cells. The hæmolytic properties of the serum can be preserved if the red blood cells are rapidly removed by centrifuging[1].

The hæmolytic process is accentuated by quinine (1 in 300), pamaquine (1 in 1,000) and mepacrine (1 in 500) and antagonized by antivenine (1 in 300); antivenine also antagonizes the action of drugs.

The clinical use of antivenine has been attended with complete success. 200 ml. initially, followed by 10 ml. at intervals of four hours, completely cut short an attack of blackwater fever in thirty-six cases, in which the mortality ordinarily would have been 25–50 per cent. Furthermore, in three cases, the administration of mepacrine in full doses together with antivenine cured the blackwater fever together with the causative malignant malaria.

## Structure of Cellulose

IN a recent communication[1], Peirce has put forward considerations on the structure of cellulose based on a pyranose ring in which the five carbon atoms are nearly co-planar and there is a right angle between the bonds of the ring oxygen. We should like to say that to invoke such a configuration is unnecessary and unjustified by the evidence. To be sure, a flat or flattish ring was long current in the X-ray literature on cellulose[2], but it was never easy to see the real need for it, and latterly Meyer and Misch[3] have stated that the X-ray intensities support the 'armchair' ring equally well and have gone over to that form.

Contrary to what Peirce suggests, the *trans*-, or armchair, form of the Sachse strainless ring does give the observed fibre period of cellulose very closely ($10{\cdot}3_7$ A. as compared with $10{\cdot}3_0$ A.), if one takes 1·54 A. for the length of the C–C bond and 1·42 A. for the C–O bond, with the tetrahedral angle for the carbon inter-bond angle and 110° for the oxygen inter-bond angle[4]. Our own immediate interest in the matter arises from an X-ray study of the structure of alginic acid and its relation to that of cellulose and its derivatives. To reproduce quite accurately the characteristic dimensional features of these two different chain configurations (and probably of pectin also), we have not yet found any necessity either for going outside such concepts of sugar chemistry as have been built up particularly by Haworth, Hirst and their collaborators, or for departing seriously from accepted bond-lengths and angles derived from simpler compounds; and full-scale models, also, that we have constructed of regenerated cellulose are satisfactory in these respects.

In support of his proposals, Peirce cites the earlier work of Cox and his collaborators: their later work, however, goes far to establish the strainless armchair ring. Cox and Jeffrey on glucosamine hydrobromide[5], for example, go almost all the way; but perhaps the most convincing evidence is found in an X-ray investigation by Cox and Brown[6] of the crystal structure of β-methyl xyloside. Here a three-dimensional Patterson synthesis reveals only three vectors of length approximately 1·5 A., and there is only one form of the xyloside molecule that is compatible with such a result, namely, the strainless armchair. The same shape of molecule provides also what appears to be a unique explanation of the observed intensities of reflexion from the ($30\bar{4}$) and (402) planes.

IT is not stated whether the new structure for cellulose proposed by Dr. F. T. Peirce[1] is in better agreement with the X-ray intensities than those previously put forward; but as some justification for it is sought in the earlier work of the Birmingham school, the following observations may be relevant. These observations are of a somewhat general character as the records of my unpublished work are not at present at hand.

At the time the paper[2] quoted by Peirce was written, X-ray technique was insufficiently advanced for detailed analyses of individual saccharides to be made, and the views advanced as to the conformation of the pyranose ring were based on a general survey of a large number of compounds. In the light of more recent work, it seems probable that as the molecular arrangement in polyhydroxy compounds is determined largely by the distribution of OH groups, whereas that in methylated sugars depends chiefly on general molecular shape, deductions from a survey covering both types are not so con-

clusive as they appeared in 1935. Later work (for example, ref. 3, but chiefly unpublished) has included very detailed analyses in which atomic positions have been fixed to rather better than 0·1 A., and within this limit there is no evidence that the pyranose ring departs from the Sachse *trans* conformation; this is not to say that I believe that small deviations from exactly tetrahedral bond angles are necessarily excluded or indeed improbable, but since the possible combinations of deviations are so numerous, it would seem to be advisable to restrict speculations on the structure of cellulose to tetrahedral configurations until experimental evidence requires some departure from them.

While I believe that the structure of cellulose will best be determined, as suggested by Peirce, by combining the knowledge of atomic arrangements found in crystalline oligosaccharides with the less detailed information obtained from cellulose itself, it must be emphasized that the assignment of atomic parameters in cellulose with an accuracy of 0·01 A. is at present entirely speculative[4], since the most detailed saccharide crystal analysis so far reported[3] gives atomic positions only to about 0·08 A., and the data from cellulose itself certainly do not justify any higher accuracy.

## Thermodynamics of Friedel-Crafts Reactions

SINCE the time of Gustavson[1] and Menschutkin[2] it has been known that salts of the $AlCl_3$ type can give stable complex compounds with certain classes of organic compound.

We have measured the heats of formation from the salt plus organic liquid of a number of these complexes. A Dewar-vessel calorimeter was used, and the results were corrected for spurious heat effects, such as those arising from chemical reactions other than complex formation. In some cases the heats are surprisingly large, and, neglecting entropy effects, it has seemed reasonable to us to ascribe an important role in these cases to the complex-formation stage, in controlling the course and products of the reaction.

For example, consider the two reactions below

$COg + C_6H_6l = C_6H_5CHOl$ . catalysed by 1 mole of $AlBr_3$ . . . . . . . . . . . . . (1)

$nCH_3Clg + C_6H_6l = C_6H_{6-n}(CH_3)_nl + nHCl$ catalysed by a small amount of $AlCl_3$ . . . . (2)

Calculation from heat of combustion and entropy data yields values of $\Delta G^\circ$ for both reactions in the neighbourhood of zero (restricting ourselves to the case $n = 1$, 2 and 3 in reaction 2). There is an uncertainty in the heats of combustion which gives an error of perhaps $\pm 1$ kcal. in case 1, and a possibly larger error in reaction 2, due to the uncertain data for $CH_3Clg$. This uncertainty is not likely to affect the point we wish to make.

In both cases no stable complex is formed between the catalyst and the reactants, and we are concerned with the products only. Considering reaction 1, we have found that the heat of formation of the complex $AlBr_3(C_6H_5CHO)_x$ is 30 kcal. per mole of aluminium bromide. It therefore seems reasonable to suggest that this complex-formation, by making the overall free energy of reaction strongly negative, plays a large part in ensuring the excellent yields normally obtainable in this reaction[3].

Our calculation for reaction 2 would suggest that, complex formation apart, none of the possible products toluene, xylenes, trimethylbenzenes should be specially favoured on thermodynamic grounds. This view is supported by the observations of Boedtker and Halse[4], on the reversibility of this reaction, carried out under normal liquid-phase conditions. However, we find that the heats of complex formation are $AlCl_3$/xylene 22 kcal.; $AlCl_3$/mesitylene 8 kcal.; and $AlCl_3$/toluene 0 kcal. Clearly, we should expect the preferential formation of the $AlCl_3$/xylene complex, and this in fact may be found under special conditions. If methyl chloride gas is passed over aluminium chloride in a vertical catalyst tube, xylene is preferentially obtained as the $AlCl_3$/xylene complex. This drips from the tube, leaving a fresh aluminium chloride surface. On the other hand, if the xylene/$AlCl_3$ complex be retained in the sphere of action by using a horizontal catalyst tube, appreciable yields of toluene may be obtained. In this latter case, similar to the usual liquid phase conditions, the xylene/$AlCl_3$ complex is formed initially, and then itself functions as a catalyst.

It is well known that the quantity of 'catalyst' used plays an important part in Friedel-Crafts syntheses; for example, whereas reaction 2 needs only small amounts, reaction 1 requires a molar quantity. Our work would suggest that two conditions determine this quantity: first, whether complex formation is necessary to make the reaction thermodynamically favourable; secondly, if a complex is formed, whether it is catalytically active. In the quantitative investigation of any particular synthesis, both factors require consideration. Equilibrium constants obtained by using catalysts of the type of aluminium chloride must be suspect unless they have been shown to be independent of catalyst concentration (for example, Pitzer's work on the xylene plus benzene reaction[5]).

## Reabsorption of Electrolytes in the Renal Tubules

REABSORPTION of electrolytes in the renal tubules has been examined for phosphates by Harrison and Harrison[1] and Smith, Ollayas and Winkler[2] in the dog, and by Barclay, Bray and Cooke[3] in man, and for chlorides by Hare, Hare and Phillips[4].

An examination of the available data at this stage may provide indication for future work and perhaps a basis for some standard system of imparting results.

We are in agreement with Harrison and Harrison[1] that the reabsorption of phosphates is directly related to glomerular filtration: if the glomerular filtration rate is plotted against the rate of phosphate reabsorption, the points fall along a straight line passing through the origin. We consider, therefore, that it is permissible to select any point on this line and use it as a reference point. The rate of glomerular filtration of 100 c.c. per minute is, we believe, convenient for two reasons: plasma values are usually expressed to 100 c.c. and, secondly, 100 c.c. would appear to be fairly close to the more recent determination of the average rate of filtration in man. On this basis, we find that the tubular reabsorption of phosphate, using a standard technique, is practically constant, but that alterations in technique do result in a different rate of reabsorption.

In the experiment of Hare *et al.*[4], we have plotted the rate of chloride reabsorption against filtration-rate, finding a straight-line relationship. Determination of the rate of chloride reabsorption per 100 c.c. glomerular filtrate shows that this is once more practically constant as is the case with phosphate; the plasma level would appear to have no influence on the rate of absorption. This is perhaps even more evident if one plots the ratio of chloride absorbed per 100 c.c. glomerular filtrate to plasma chloride, instead of the ratio used by the authors. Thus plotted, their Fig. 2 is considerably altered; 2·5 per cent sodium chloride falls well below 0·5 and 0·6 per cent sodium chloride. This is merely another expression of our point that a rise of plasma chloride does not affect the rate of reabsorption. If a similar procedure is adopted in the case of their Fig. 3, it is at once evident that pituitrin has no effect upon the rate of tubular absorption of chlorides. Hare *et al.* noted that if glomerular filtrate was increased, the reabsorption of chloride is increased; when they state that they can find no upper limit to the threshold, they merely indicate that the tubules are able to cope with the increased chloride provided by the increased filtration to limits set by the inability of the organism to tolerate further increase of sodium chloride. When they state that they are unable to find a threshold value for chlorides, we would point out that the threshold, expressed as a rate of tubular reabsorption per 100 c.c. glomerular filtrate, is in the neighbourhood of 380 mgm. per 100 c.c. The reason for the increased excretion of chlorides during the glycosuria experiments would appear to be the lowering of the chloride threshold to 330 mgm. per 100 c.c. If one uses the method of ratios, when the reabsorption per 100 c.c. glomerular filtrate to the plasma value is less than one, then the threshold has been exceeded.

The use of percentage chlorides reabsorbed is preferred by Hare *et al.* rather than the absolute amount reabsorbed, presumably because they feel that the percentage is more constant than the absolute amount. This is, of course, a point of fundamental importance from the point of view of renal function. We have indicated above our reasons for preferring absolute amounts, but perhaps further examination will clear the way to future discussion. Evidence against a constant percentage absorption of chlorides is provided by the authors' own ratios. In the dogs with diabetes insipidus, the ratio is high; on administration of pituitrin, the ratio falls. Careful consideration of the figures indicates that the difference in the ratios is due to the fact that while the diabetes insipidus dogs are reabsorbing less water, they are, as we pointed out, reabsorbing the same amount of chloride, and therefore the percentage of chloride must be high and so must be the ratio. If the percentage of chloride reabsorbed remains constant, then the excretion of chloride will vary directly with the volume of urine; if the absolute amount remains constant, then excretion will vary directly with the plasma chlorides. Since Hare *et al.* point out that even when plasma chloride has fallen considerably, chloride is still present in the urine, and Smith[5] also makes the same point, perhaps it is as well to indicate the conditions which must be fulfilled if the urine is to become chloride-free. If the amount of chloride reabsorbed per 100 c.c. glomerular filtrate is the same as the plasma chloride, the urine will be free at all filtration-rates and all urine volumes; if the percentage of chloride is constant, then urine will be chloride-free only for a certain definite percentage (higher than the plasma value), and for a certain definite filtration-rate and urine volume.

In either hypothesis the variability of the factors involved makes the likelihood of obtaining a chloride-free urine very small indeed.

To summarize, we believe that the electrolytes, at any rate those so far examined, have a definite threshold, but this threshold is not fixed once and for all, but, save under rigidly standard conditions, varies from time to time, probably under the influence of hormone balance. It does not appear to vary with the level of the electrolyte in the blood, although Smith, Ollayas and Winkler[2] have demonstrated an effect on threshold when the plasma-level is outside the normal physiological range. Lastly, the excretion of electrolytes, like that of water, is practically independent of rate of glomerular excretion; and the tubule cells have apparently no upper limit to the amount they can reabsorb from an increasing glomerular filtration.

## Permanence and Stability of Emulsion Systems

THE terms 'permanence' and 'stability' have often been regarded as synonymous when applied to emulsion systems. Until recently, neither term had a sufficiently rigid significance. In 1939, King and Mukherjee[1] defined the stability of an emulsion system as the reciprocal of the rate of change (with respect to time) of interfacial area, per unit area of initial emulsion interface. In this connexion the term 'specific interfacial area' ('specific surface', 'specific interface') may be expressed as being the number of square decimetres of interfacial area per gram of the dispersed liquid. These authors assumed that the rate of change of specific surface of an oil-water

emulsion is proportional to the initial specific surface (although in later work[2] they found that there appeared, in some cases, to be two rates, an initial rapid change, followed by a slower change), that is, according to the simpler assumption,

$$-\frac{ds}{dt} = k_1 s_1 = \frac{s_1}{k},$$

where $s$ is specific surface; $s_1$ is initial specific surface; $t$ is time; $k_1$ is instability factor; $k$ is stability factor.

It will be observed that $k$, here, has the dimension of time. King and Mukherjee developed a method, based on the size-frequency analysis of the given emulsion system after various time-intervals, for the evaluation of $k$.

Lotzkar and Maclay[3] determined the comparative efficiencies of certain emulsifying agents by the application of a size-frequency technique to the emulsions formed using these agents, but the formula used in calculating the stability factor ($k$) of the emulsions was modified to:

$$-\frac{ds}{dt} = k_1 s = \frac{s}{k}.$$

In this formula also, $k$ has the dimension of time.

In many technical processes emulsions are required to withstand such mechanical stresses as those imposed by shaking, vibration, centrifuging, temperature-change, impact, etc.

It is conceivable that where precaution is taken against the submission of the system to undue mechanical or other disturbance, an emulsion might display a high degree of permanence inasmuch as that comparatively little deterioration might occur on ageing; whereas if it were subjected to some disturbance rapid deterioration might set in.

Such a system (a water-oil emulsion, sponsored by Mona wax) is described by Aherne and Reilly[4]. The emulsion, "a water-in-liquid-paraffin system", showed good permanence inasmuch as that no gross deterioration could be observed when it had aged for months, but even the most cautious addition of a light cover-glass to a sample of the emulsion (suitably diluted) on a microscope slide caused immediate coalescence of the water-globules of the sample in 'pools'. It is therefore questionable whether the terms 'stable' and 'stability' could, even in the ordinary restricted sense (since de-emulsification is, in the thermodynamic sense, an irreversible process), be applied to a system unable to withstand such slight mechanical disturbance. If the factor obtained as a result of size-frequency analyses at various time-intervals (precaution being taken against the submission of the system to undue mechanical disturbance) be called, in the case of such a system, a 'stability factor', the figure might be very misleading. It has been suggested, therefore, that the factor $k$ (above) might, when the precaution aforementioned is taken in its determination, be termed a 'factor of permanence'.

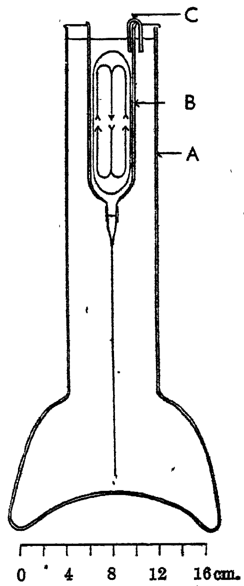
## An Apparatus for Low-Temperature Dialysis

BOTH speed and low temperatures are highly desirable in the dialysis of sensitive protein solutions. Unfortunately, when small refrigerators are used instead of cold rooms, the apparatus used to increase the velocity of dialysis has to be sacrificed to space requirements. For example, the Kunitz[1] dialyser, in which a stream of pure water is allowed to flow over a rocking dialysis sac containing a marble, cannot be set up in an ordinary laboratory refrigerator.

If a dialysis sac containing a salt solution is suspended in water, the greater density of the solution dialysing out causes it to flow downwards, and currents can be seen streaming away from the bottom of the sac. In the dialyser described below, an attempt has been made to utilize this fact to set up a circulation which results in a constant supply of fresh water to the outside of the dialysis sac. The apparatus consists of a tall dialysis vessel $A$ of about 7·5 cm. diameter by 40 cm. high containing a second flow-directing vessel $B$ about 15 cm. total length by 3·5 cm. in diameter ending in a jet. The dialysis sac is placed in the inner vessel, and the water in the inside and outside vessels connected by a syphon $C$ of approximately 2 mm. bore.



The flow of the denser salt-containing fluid out through the jet can be easily followed either by direct observation or by placing a flash-lamp bulb on one side of the vessel about 1 ft. away and a sheet of paper on the other side at a similar distance, when a Schlieren picture of the stream will be projected on to the paper. The fine stream of fluid from the jet passes almost to the bottom of vessel $A$ without breaking up, and even after it has broken up the fragments continue on their way downwards. This flow results in the dense salt solution collecting at the bottom of vessel $A$, while fresh water is being continuously supplied around the dialysis sac. The process lasts for 24–48 hours, depending on the initial volume and concentration of the dialysing fluid, and continues until the salt solution has risen to the level of the jet.

Simultaneously, another circulation is taking place inside the sac. It can be observed by watching the movement of small particles of dust, etc., just inside the membrane, where the fluid, owing to loss of salt, rises slowly, while that in the centre of the sac falls, resulting not only in mixing inside the sac but also in the maximum differential salt concentration being developed across the membrane due to the counter current principle. The flow of fluid inside and outside the membrane also helps to abolish skin effects which restrict diffusion due to stagnant surface layers.

The dimensions of the apparatus, especially height of vessel $A$ and jet size, play an important part in efficiency. We have not observed unbroken flow

streams of more than 20 cm. from jets used, and it therefore seems that no great increase in efficiency would result from making the apparatus any taller. The optimum diameter of the jet appears to be about 0·4 mm.

The dialysis time for a 0·5 saturated ammonium sulphate solution under these conditions is about thirty hours, and the final concentration inside the sac is approximately 1/500 of the initial concentration, that is, of the order of 0·1 mgm. nitrogen/c.c. This dilution corresponds to 1/12 of the concentration that would occur if all the salt in the sac were to be evenly distributed throughout the whole volume of the dialysate.

To avoid salt contamination of the water in the outside vessel, the apparatus is set up as follows. The dialysis sac is placed inside vessel *B*, and *B* is then lowered into *A*, which already contains the approximately correct volume of water. When the inside and outside levels are the same, the syphon is filled and dropped into place.

The term 'gravity dialyser' is suggested for the apparatus.

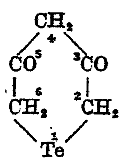
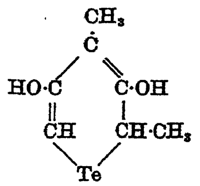
## A Speculation on the Bactericidal Activity of certain Tellurium Compounds

THE intense bactericidal activity of *cyclo*telluropentane-3 : 5-dione (I) and some of its homologues was reported by Morgan and his collaborators[1–4]. This property is shared only to a limited extent by other tellurium compounds; it is not due to the lability of tellurium in this ring, since conversion of (I) into its equally labile dioxime causes a marked drop in bactericidal power (see table). The theory of substrate competition[5] provides a rational explanation of the activity of this group of compounds. The formula of one of the highly active members, 2 : 4-dimethyl-*cyclo*telluropentane-3 : 5-dione (II), bears a striking resemblance to that of pyridoxine (III), which is known to be a growth-factor for many species of micro-organisms[6–8], and it seems to us possible that the relation between the two substances may be similar to that between *p*-amino-benzoic acid and sulphanilamide[9,10].

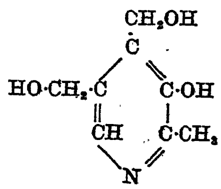
In the present circumstances, we are unable to test this hypothesis experimentally; but the following facts may be adduced in its support, the data on *B. coli communis* being drawn from the table. Similar results are available[2] from experiments on *B. typhosus*, *Staph. pyogenes aureus* and *Strep. hæmolyticus*.



(I)



(II)



(III)

(i) The bactericidal effect requires the presence of an enolic hydroxyl group in the 3-position of the *cyclo*-telluropentane-3 : 5-dione ring. When enolization is prevented (the dioxime) or inhibited (the 4 : 4-diethyl compound) the effect is less marked. A hydroxyl occurs in the corresponding position of the pyridoxine molecule.

(ii) The bactericidal effect is sensitive to the nature and position of substituents in the *cyclo*-telluropentane-3 : 5-dione ring. The 1 : 1-dihalides are inactive and the strongly polar 4-chloro-compound has only very weak activity. Unsubstituted *cyclo*telluropentane-3 : 5-dione is moderately effective, but the introduction of small alkyl groups (methyl or ethyl) in the 2-position greatly enhances the bactericidal power; larger alkyl groups (propyl, butyl or amyl) are less effective. A methyl group in the 2-position characterizes the pyridoxine molecule.

Pyridoxine bears an alkyl substituent in the 4-position, and 4-alkylated derivatives of *cyclo*-telluropentane-3 : 5-dione are considerably more active than the parent substance. The 2 : 4-dimethyl compound is second equal in activity in the series which was tested.

If the arrangement N.C($CH_3$).C(OH).C may be regarded as of fundamental bacteriological significance in the pyridoxine structure, it should be noted that the most active tellurium derivatives tested, 2 : 6-dimethyl and 2 : 6-diethyl *cyclo*telluropentane-3 : 5-dione, contain this arrangement twice, nitrogen being replaced by tellurium.

| Compound | Mean effective concentration |
|---|---|
| *Cyclo*telluropentane-3 : 5-dione (CTPD)[2] | 1 in 500,000 |
| CTPD-3 : 5-dioxime[4] | 1 in 166,000 |
| 4 : 4-Diethyl CTPD[2] | 1 in 900,000 |
| 4-Chloro-CTPD[11] | 1 in 12,500 |
| 2-Methyl CTPD[2] | 1 in 3,000,000 |
| 2-Ethyl CTPD[2] | 1 in 3,000,000 |
| 2-Propyl CTPD[2] | 1 in 1,200,000 |
| 2-Butyl CTPD[2] | 1 in 700,000 |
| 2-Amyl CTPD[2] | 1 in 500,000 |
| 4-Methyl CTPD[2] | 1 in 900,000 |
| 4-Ethyl CTPD[2] | 1 in 2,500,000 |
| 4-Butyl CTPD[2] | 1 in 2,800,000 |
| 2 : 4-Dimethyl CTPD[2] | 1 in 5,000,000 |
| 2 : 6-Dimethyl CTPD[2] | 1 in 9,000,000 |
| 2 : 6-Diethyl CTPD[2] | 1 in 5,000,000 |

Should our general hypothesis be correct, it seems possible that compounds related to *cyclo*telluropentane-3 : 5-dione, but containing oxygen or sulphur instead of tellurium, might have correspondingly high bactericidal or bacteriostatic properties without the alarming toxicity which makes *cyclo*telluropentane-3 : 5-dione itself quite impossible for therapeutic use.

# RESEARCH ITEMS

## Carbohydrate Metabolism after Burns

IT is well known both in man and animals that there is a rise in the level of blood sugar during the first few hours after a burn. E. J. Clark and R. J. Rossiter (*Quart. J. Exp. Physiol.*, 32, 269 and 279; 1944) have studied the changes in carbohydrate metabolism produced by experimental skin burns in rats and rabbits. During the first three hours following a burn there is hyperglycæmia, rise of blood lactate, decrease of muscle glycogen, and either no change or a decrease in liver glycogen. The increased blood sugar comes chiefly from the muscle glycogen via the liver (Cori cycle). All these changes, except for the liver glycogen, could be reproduced by injection of adrenaline into normal animals. Injection of adrenaline into rats and rabbits always causes a rise of liver glycogen. Further, it was shown that liver slices from the burned animals formed glycogen from glucose (*in vitro*) much less readily than did liver slices from normal animals, whereas liver slices from adrenaline-injected animals formed glycogen normally. The authors conclude that the changes are mainly due to the liberation of adrenaline, but that in addition there must be some other factor acting on the liver, either accelerating glycogen breakdown or inhibiting its synthesis. Results of other workers suggest that some factor in addition to adrenaline is also at work in the hyperglycæmias of hæmorrhage and asphyxia. There is no clue as to what the additional factor may be, but it is probably common to burns, hæmorrhage and asphyxia.

## Spanish Mackerel

CAPTAIN IAN S. R. MUNRO has published a most useful work in his "Revision of Australian Species of Scomberomorus" (*Mem. Queensland Mus.*, 12, Part 2; Nov. 1943). The Spanish mackerel comprise an important group of deep-sea food fishes which support a valuable coastal pelagic fishery in Australian waters, particularly Queensland, northern New South Wales and Western Australia. The industry is based primarily on the barred Spanish mackerel *Scomberomorus* (*Cybium*) *commerson*, caught by trolling in coastal waters, but there is a small net fishery of *Scomberomorus* (*Cybium*) *queenslandicus* sp. nov., which enters the estuaries along the coast during the winter months. Several other marketable species are caught in smaller numbers. All these, like their relatives from overseas, are first-class food fishes, and the larger forms provide good sport for game anglers along the coast of New South Wales and the Great Barrier Reef. A decline in the annual catches in spite of improvement in technique and equipment is due partly to a large increase in fishing activities during the spawning seasons. Investigations concerning the biology and economics are in progress, and the present work deals with the exact diagnosis and subsequent identification of all species. Four species are shown to occur in Australian seas. All members of the family are coastal inhabitants, and throughout the world they are seldom found in water deeper than forty fathoms. Some migrate into estuarine waters at certain seasons. Most of the species inhabit the clear tropical waters of ocean currents around rocky islets and coral reefs, tide rips and off-shore currents. Their preference for waters of low density and medium salinity apparently accounts for their coastal distribution. Good figures of the Australian species are given.

## Carbon Dioxide as a Measure of Grain Infestation

R. W. Howe and T. A. Oxley of the Pest Infestation Laboratory at Slough discuss a method intended to give at least an approximate measure of insect infestation of grain in a short time. In this connexion it was thought that the rate of carbon dioxide production of infested grain, as a measure of metabolism, would probably be a satisfactory measure of infestation. The very different methods in use are either laborious or consume a great deal of time. While the carbon dioxide method gives less detailed information than the existing and more laborious methods, it has the great advantage over them of giving an estimate of the actual amount of damage which an infesting population is causing. The authors describe (*Bull. Entomol. Res.*, 35, 11; April 1944) a detailed technique for the routine determination of the carbon dioxide output of samples of grain. The carbon dioxide figure obtained is largely a measure of insect infestation of the sample of grain tested, and a table is given by which the numbers of various species of grain infesting insects may be estimated from the carbon dioxide figure. Clean grain of less than 15 per cent water content produces up to 0·25 per cent carbon dioxide in twenty-four hours at 25° C., so that results up to 0·3 per cent are considered to indicate clean grain. A result between 0·3 and 0·5 per cent indicates slight infestation or a water-content of more than 15 per cent. Grain showing a carbon dioxide content of 1 per cent or more indicates that it is highly unsuitable for storage. In such a sample this is an indication of an infestation of one Calandra weevil larva per 500 grains or 33 larvæ per pound.

## Embioptera or Web-spinners of the New World

IN the *Proceedings of the United States National Museum*, 94 (1944), E. S. Ross gives an admirable review of the systematics of the Recent and Tertiary species of the insect order Embioptera of North and South America. Some 71 American species are recognized and these are distributed in 17 genera and 6 families. All the genera excepting Oligotoma seem to be endemic to the New World. The systematics of the order are almost entirely based upon the characters of the males. The females are neoteinic to a great extent and show but few characteristics. So far no features have been discovered to enable the genus or even the family of the females or of immature specimens to be identified. The best, or almost the only means, is to identify these by their definite association with known males. It is interesting to note that in the New World there are in the Clothodidæ species showing the most generalized structural features of the order, and in the genera Oligembia and Chelicerca those showing some of the highest specialization. The memoir, which extends to more than one hundred pages, includes 156 very clear text-figures illustrating structural details of the various species together with one photographic plate of wing venation. A work of this kind greatly aids in the identification of the insects concerned, and it is hoped that it will stimulate field collectors and students to devote attention to this peculiar but neglected order of insects.

## Witches' Broom of the Cacao

AN interesting study of the ecology of a parasitic fungus is described by R. E. D. Baker and S. H. Crowdy (Memoir No. 8, Dept. of Mycology and Bacteriology, Imp. Coll. Trop. Agric. Trinidad, Jan.

1944). The paper deals with field studies and control methods of the witches' broom disease of cacao, caused by *Marasmius perniciosus*. The malady has assumed serious proportions of recent years, and several types of broom have been described in earlier publications. Broom formation is maximal in January or February, and minimal in June or July. Cacao trees bloom all the year round, and cushion brooms are strongly and positively correlated with the numbers of flowers at any one time. The disease appears to be more closely associated with flowering than with vegetative growth. Shoot growth flushes five or six times a year, and fan brooms appear with the flush, though the total amount of shoot growth has little effect upon the numbers of brooms. It can apparently affect pods only at an early stage of development. Eradication of the fungus by direct methods does not appear to be feasible, and the search for immune or highly resistant varieties of cacao seems to provide the only practicable possibility of control.

### Development of the Eye in Drosophila

A. G. STEINBERG (*Proc. U.S. Nat. Acad. Sci.*, **30**, 5; 1943) has shown that the character 'bar eye' in Drosophila is controlled by the reduced size of the eye disk in embryo and by the fate of labile cells in the larval stage. These cells may either take part in eye formation or be transformed into chitin, according to the influence of external or internal causes. For mutants such as the 'lobes' and 'eyeless' in *D. melanogaster*, it would be interesting to know whether they developed in a similar way. Steinberg provides evidence that this is the case.

### Electrical Resistance Strain Gauges

A PAPER read recently in London by S. F. Dorey before the Institution of Mechanical Engineers deals with the measurement of static strains using electrical resistance strain gauges in conjunction with a Wheatstone bridge, and having a cathode ray oscillograph instead of the usual galvanometer. The advantages of this arrangement are indicated in the paper, and it is shown that stresses so low as 250 lb./sq. in. can be measured readily under workshop conditions, provided the correct technique is applied. Methods of calibration of this equipment and also its use in two specific problems are described.

### Bonding and Earthing of Single-Core Cables

AN article by E. A. Beavis and C. W. Schofield (*Eng. Supp. Siemens Magazine*, No. 216, April/May 1944) discusses the provisions which should be made for the bonding and earthing of metal-sheathed single-core paper-insulated lead-covered cables in three-phase installations. The subject is considered from the points of view of the sheath voltages which arise when the cables are bonded and earthed at one point only, and of the circulating currents which flow along the sheaths when multiple bonding and earthing is employed. The type of installation to secure minimum transmission losses, characteristics of various types of installations, earthing and bonding for various types of installations, and theoretical considerations of induced voltage and sheath current are discussed and, finally, the authors give some practical test results. The investigation covers cables for voltages of from 1 kV. to 33 kV., of cross-sectional areas of 0·25–1·5 in.$^2$ according to voltage, and at cable spacings ranging from 2 in. to 120 in. Provided sheath voltages are not allowed to reach dangerous values, especially under fault conditions, it is concluded that earthing and bonding at one point is the ideal arrangement.

### Flow of Current between Electrodes on a Metal Surface

A PAPER by the late Prof. W. M. Thornton describes investigations carried out on this subject (*J. Inst. Elec. Eng.*, **91**, Pt. 2, No. 20; April 1944). Measurements of the thickness of metal plates or tubes from one side only can now be made by a direct-current electrical method. In the 'four points in line' method a low voltage is applied by point contacts to the surface and the potential drop between them observed. In B. M. Thornton's 'six points in line' method there are two pairs of points on which the potential is observed, and in Warren's 'eight point' method the electrodes are arranged in two squares. On account of the spread of the current, the readings on the potential points differ and their ratio is an indication of the thickness of the plate. The six- and eight-point methods give values for the thickness that are independent of the resistivity of the metal. The theory of the flow of current between two electrodes in an infinite plate is well known; but the surfaces to be examined for thickness are in practice restricted in area and have boundaries which are not always of regular shape. The influence of proximity of the electrodes to a free edge has been previously examined. The paper deals with the flow of current between point electrodes in circular and elliptical areas, a square, a rhombus, narrow and wide lenticular areas and a narrow lune. The flow between points on the surface of metal tubes is considered. Results obtained by the 'six points in line' method are quoted and a collection of derived formulæ is added.

### Flow of Fluid through a Nozzle

THE equations of motion of a compressible fluid, such as steam, through a nozzle present great difficulty even when the fluid is assumed to have no viscosity. Osborne Reynolds's well-known treatment (1886) applied only to the one-dimensional case when the velocity was uniformly distributed over each cross-section. In two dimensions very few exact solutions are known, and these relate to cases which are not realizable in practice. Rayleigh (1916) proposed a method of successive approximations. Taylor and Sharman (1928) used an electrical analogue to obtain solutions by experiment; their method failed when the speed exceeded the local speed of sound. A recent paper by J. R. Green and R. V. Southwell (*Phil. Trans. Roy. Soc.*, A, **239**, 367; 1944) gives an approximate numerical method based on Southwell's general method of 'relaxation', which he has applied to a whole series of engineering problems. Given the shape of the nozzle, the first step is to use a conformal transformation of this shape into a rectangle. The exact differential equations are replaced by approximate equations of finite differences, which are easier to solve. Then, in accordance with the relaxation technique, the error of these approximations is expressed in terms of 'residual forces', and finally these 'forces' are 'liquidated', that is, reduced to negligible magnitudes. Like the electrical method, the relaxation method fails when the speed exceeds that of sound. An alternative method, not yet fully worked out, is proposed to deal with this case.

# AMINO-ACID MIXTURES AS AN ADDITIONAL FOOD FOR PREMATURE INFANTS

By J. HENNING MAGNUSSON
Pediatric Clinic attached to the Caroline Institute, Norrtull Hospital, Stockholm

IT is generally agreed that human milk is far superior to all other foods for premature infants, and this form of nutriment seems to be one of the essentials for a low mortality. As a rule, however, these infants have begun their extra-uterine life far too early, and in their case, therefore, breast milk cannot be said to be the ideal nourishment to the same extent as it is for those born at term. In the rearing of premature infants, also, there is the question of supplying food in sufficient quantities to be met, a factor which need not be considered with full-term babies. This difficulty is especially noticeable in the case of small infants whose weight at birth is considerably below 2,000 gm. To cover the high calory requirements of these infants solely by means of human milk, with its 70 or so calories per decilitre, places a high demand not only on the holding capacity of the stomach but also on the digestive organs as a whole. It should be remembered, also, that in nearly all premature infants the digestive organs are functioning below par, during the first weeks at least.

Because of the tendency of these infants to develop acute inanition, a regular feeding regimen must be started early; but only small amounts of breast milk can be given during the first days. The amounts supplied must be kept strictly within the limits of the minimal food requirements for life, and overfeeding must be as conscientiously avoided as underfeeding. Increases in food are made only very gradually, and the smaller and the more premature the infant the greater the care which must be exercised. Further increases in amount are based on the weight of the infant and on the infant's food tolerance.

When the premature infant is fed on human milk, the weight curve, after the initial drop, not infrequently remains almost horizontal for the first three, or even four weeks of life. After that, it begins gradually to rise, so long as no complications, in the form of intercurrent infections, arise.

Various supplementary foods have been tried with the view of increasing the calories the infant receives through the breast milk. In the majority of cases these have consisted of small feeds of a concentrated cow's milk mixture, the main purpose with these being to meet the large requirements of mineral salts and protein. Other observers have tried additional feeds of casein or glucose, or a mixture of both of these.

The premature infant requires a diet which is readily assimilable and rich in proteins. An amino-acid mixture ought to be capable of fulfilling these conditions, especially in view of the fact that amino-acids of low molecular weight are absorbed as easily as sugar while whole protein molecules are not absorbable. There is also reason for believing that infants at this early stage of development have an imperfectly functioning enzymic mechanism, and that, because of this, they cannot properly assimilate the ordinary foods. If this is really the case, then the unsatisfactory gain in weight so often observed during the first weeks of life must be nothing more or less than a sign of starvation.

Since November 1943, I have been experimenting with amino-acid mixtures as a supplement to human milk. More than thirty infants have been treated, and uniformly good results have been obtained. In the pediatric literature which has found its way to Sweden under the present war-time restrictions, I have only succeeded in finding two reports on the use of amino-acids as an additional food for young infants[1,2]. The feeding of amino-acid to prematurely born infants, on the other hand, does not seem to have been tried.

The amino-acid mixture used is 'Aminosol', manufactured by Vitrum, of Stockholm, a preparation worked up by Drs. E. Jorpes and K. A. J. Wretlind, of the Department of Chemistry, Karolinska Institutet. It is prepared by enzymic disintegration of casein followed by dialysis of the amino-acids, and it contains 80–85 per cent free amino-acid. As the yield of the starting material is 80–100 per cent in this preparation, the amino-acid content can be said to be the same as in casein. Glucose was added to the amino-acid mixture in order to supply calories. To meet the salt requirements, Osborne-Mendel salt mixture was also added. Thus the preparation used in my experiments ('Aminosol'-glucose) had the following composition: amino-acid mixture 25 per cent, glucose 25 per cent, and salt mixture 1·5 per cent.

In most instances the mixture was given through a catheter concurrently with the breast milk during the first days, or weeks, of life, and later by the oral route. The question of dosage has not yet been definitely established. As a rule, the daily dose given

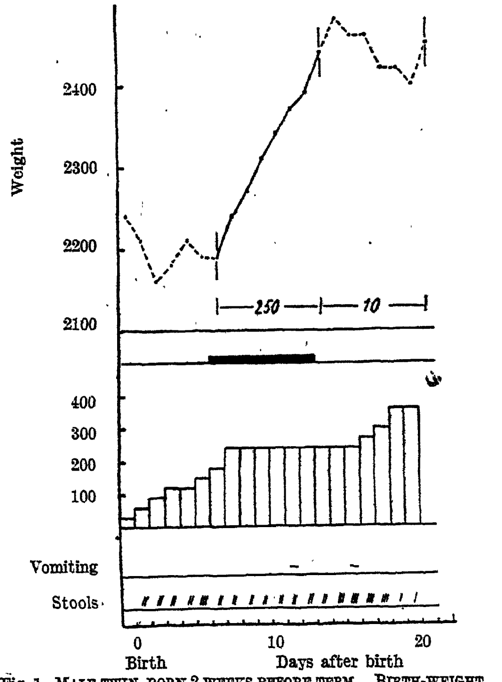

Fig. 1. MALE TWIN, BORN 2 WEEKS BEFORE TERM. BIRTH-WEIGHT, 2,160 GM.

In the weight curve, - - . - - - . - - - . indicates periods during which the infant received breast milk only, and . — . — . periods in which it was supplemented by 'Aminosol'-glucose. The figures between the vertical lines below the weight curves show the weekly gain in weight, and equals 'Aminosol'-glucose (10 c.c. daily per kgm.) as additional food.

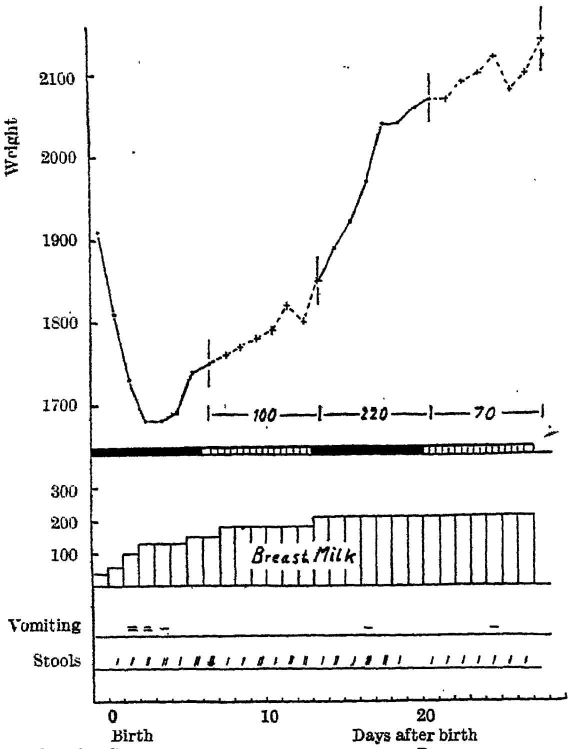

FIG. 2. GIRL, BORN 1 MONTH BEFORE TERM. BIRTH-WEIGHT, 1,960 GM.

In the weight curve, + - - + - - indicates periods in which the infant received, in addition to the breast milk, undigested casein plus glucose plus salt mixture, and the 'ladder' below indicates the amount of this mixture (10 c.c. daily per gm. body weight) which was fed.

was 10 c.c. of 'Aminosol'-glucose per kgm. of body weight. This amount was almost invariably well tolerated by even the smallest of the infants without any complications arising in the form of vomiting or digestive disturbances. With some infants half this dose was sufficient to produce a good gain in weight. The cases cited below are appended to illustrate the results.

Some data are presented in Fig. 1.

It cannot be asserted with certainty that the greater gain in weight occurring while the infant was receiving the additional feeds of 'Aminosol'-glucose was due exclusively to the amino-acid mixture, although from the physiological point of view it would seem obvious that this was the cause. One objection that may be raised against this assumption is that the infant was receiving more calories during these periods and that the gain in weight was due to this fact. In order to clear up this point, a series of tests was made in which the effect of feedings of 'Aminosol'-glucose was compared with the result obtained from a mixture containing undigested casein, glucose, and mineral salts of the same strengths and in the same proportions as in 'Aminosol'-glucose. The only difference in the two foods was that the amino-acid mixture was exchanged for undigested casein. Some results are shown in Fig. 2.

In all the tests in which the effect of the amino-acid mixture was compared with that of undigested casein, the gain in weight was much greater in the periods during which the amino-acid mixture was being fed. Thus the amount of calories we supplied through this additional food cannot in itself have been the reason why the infant put on so much extra weight. The cause is undoubtedly to be sought in the feeding of amino-acids. To judge from certain cases, it would almost seem as if the amino-acids are used quantitatively for protein synthesis, since the daily weight increase was approximately equal to the gain in weight which would be obtained through protein synthesis and binding of the corresponding amount of water.

# TEACHING OF PLANT GENETICS

ON February 20, 1943, Dr. W. Burns, agricultural commissioner with the Government of India, delivered his presidential address to the Indian Society of Genetics and Plant Breeding on the subject of the teaching of plant genetics in India (*Indian J. Genetics and Plant Breeding*, **3**, 1; 1943). His comprehensive survey and discussion of this question, based as they are on a wide experience of the application of genetics to Indian agriculture, call for consideration in some detail.

Dr. Burns thinks that the rudiments of genetics should form part of the liberal education of those who proceed beyond the secondary school, because our behaviour and reaction to many situations must be profoundly affected by our understanding of the part played by heredity. A general raising of the level of biological teaching in schools is one of the essential prerequisites of teaching genetics and would enable "the future citizen, administrator or specialist to handle problems dealing with living things, including man, less ignorantly". The specialist in biology, medicine or agriculture requires, of course, a wider knowledge of genetics, since there are few biological problems the genetical aspects of which can be safely neglected. The plant breeder must have available to him all the resources of genetical science.

Genetical teaching is bound to be affected by the rapid and, in some ways, uneven growth of the subject. The necessary perspective could be introduced by a short historical survey. Elementary courses in genetics should aim at making clear the basic concept of the genotype and the chromosome theory of heredity, and should be preceded by a botany course and an introduction to biometrical mathematics. Instruction in cytology should be included in the botany course, and should involve the making of simple preparations of dividing nuclei. Practical work in elementary genetics itself would of necessity be largely on prepared material in the laboratory.

The biological specialist requires an additional preliminary course in floral biology to acquaint him with the structure and action of different floral mechanisms, the operation of incompatibility, and the methods used in making controlled pollination by artificial means. The genetical course itself should begin with a biometrical study of naturally occurring variation, proceeding via the distinction between heritable and non-heritable variation to Mendelism and chromosome theory. The student should count

segregating families and so be led to an understanding of sampling variation and tests of goodness of fit. Finally, the bearings of genetics on evolutionary theory and taxonomy should be made clear, with special reference to complex, or polygenic, inheritance. This would require that the teachers themselves should have studied the problem carefully, and should have "some form of belief and not merely a chaos" in their minds. Dr. Burns also recorded a protest against the tyranny of the herbarium method and a plea for a fuller study of living plants in taxonomy.

With reference to the plant breeder, it is clear that he should receive a fuller mathematical training than the other classes of student, for otherwise he must acquire it "painfully, perhaps self-taught" at a later and less convenient stage. He should also have a more comprehensive course in genetics, though it could be modelled on the lines sketched earlier. He would require an introduction to the modern theory and practice of field experiments, with practical work involving responsibility for an actual trial. The part to be played by statistics was discussed in relation to the danger of an undue adherence to statistical methods leading to a neglect of the living plants. The solution is essentially that of training the breeder to rely primarily on observations of, and familiarity with, his crop; and to show him how his observations can be amplified and checked by statistical analyses.

Dr. Burns concluded with a survey of the present position of genetics teaching in India, which he found far from satisfactory. He advocated the giving of preliminary instruction in the universities and of advanced courses in agricultural institutes. Above all, if this genetical teaching is to be fruitful the students must be led to grow plants and study them as living things. The provision of facilities for this should not be too great a tax on the resources of educational establishments; but there is a need for a small hand-book of practical genetics using the plants, chillies, rice, etc., with which Indians are familiar.

This discussion of teaching in plant genetics is noteworthy in a variety of ways, but especially perhaps for its insistence on the following points:

(1) The argument for the wider teaching and appreciation of general biology and the genetical point of view.

(2) The introduction of perspective into genetics by the approach through observable variation in Nature and the linking of genetics to evolutionary theory and taxonomy.

(3) The need for preliminary courses in floral biology and mathematics, and the introduction of modern statistical methods into the teaching.

(4) The emphasis on relating genetics teaching to the living organism as a corrective to over-formalization.

It must be remembered that Dr. Burns was discussing plant genetics in India, and so his various points may not apply with equal emphasis to all genetics in all countries. His separation of cytology from genetics and its inclusion in the botany course, for example, will not be desirable everywhere. Nevertheless, his conclusions and proposals merit the careful study of all who are concerned with genetics and its teaching. His remarks are indeed especially timely in view of the expansion of genetics and genetical teaching which must now be contemplated in Great Britain.

# GEOLOGISTS IN THE POST-WAR PERIOD

THE total number of British geologists wholly engaged in a professional capacity in pre-war years was probably less than six hundred, nearly one quarter of whom were occupied in the teaching of the science, principally in the universities. To some extent this high proportion of geologists engaged in academic spheres is due to the fact that large classes of technical students in mining, metallurgy, civil engineering, and agriculture require tuition in geology as a part of their professional training.

The Geological Society of London has recently given evidence on the post-war recruitment of professional geologists, to the Inter-Departmental Committee on Further Education and Training, under the chairmanship of Lord Hankey. After expressing the hope that geology should be introduced into the schools as a fundamental study in general science courses, the Society stressed the important part that geologists play in the discovery and development of mining fields and oilfields, and in many branches of civil engineering.

In spite of the importance of geological work, the normal pre-war number of fully-trained geologists graduating each year from British universities is only about thirty. Although there have been wide fluctuations in the demand for mining and oil geologists, as a result of trade cycles, the supply of suitable men has usually been inadequate. It is probable that there will be a still greater dearth of British-trained geologists in the immediate post-war period, owing to the requirements of industry, Government Geological Surveys, and university teaching staffs. Within two years after the cessation of hostilities, it seems likely that considerably more than a hundred recruits will be called for to fill gaps and augment the ranks of professional geologists. It is certain that as soon as the War ends, there will be a demand for more men on the Geological Survey of Great Britain and the Colonial Geological Surveys.

Owing to impending retirements and proposed expansion of staff, there will be an immediate call for not less than ten men on the Geological Survey of Great Britain, with further recruitment in succeeding years. Representations have been made to the Secretary of State for the Colonies by the Geological Society and the Institution of Mining and Metallurgy, and it is confidently anticipated that many additional geologists will be enrolled for the staffs of the Colonial Geological Surveys. Not only is there a need for pressing on with routine geological mapping in the Colonies, but there is also great scope for more work to be done in connexion with the development of mineral resources, water supply, public works (dams, reservoirs, harbours, roads, etc.), and soil conservation. It has also been pointed out that several heads of university geological departments must soon be retiring under the age limit, and a number of junior posts in these departments will also be vacant. Within recent years new avenues of employment for geologists in industry have been opening up.

There are ample opportunities for trained geologists in the British oil companies, which face immediate post-war projects necessitating the employment of geological staffs larger than heretofore. Oilfields in Burma and elsewhere in the Far East will have to be re-opened, and studies must be made of the effect of Japanese operations, and of the best means of re-

suscitating the oilfields. To offset damage to operating fields, exploration to discover new ones must be accelerated. British interests, whether co-operating or competing with those of the United States, must enlarge their fields of action, and they will need to engage large staffs of oil geologists to do this effectively. Moreover, geologists in oil companies are continually being attracted out of the exploratory phase into production and field management.

In addition, after the War there is likely to be a widespread development of young mining fields and a general exploration for new metallic and non-metallic mineral deposits, which will involve the services of many mining geologists. Such men must also be recruited into the Government Geological Surveys in greater numbers than has hitherto been the practice.

## GRAVITATION, ELECTROMAGNETISM, AND QUANTUM THEORY

A RECENT paper by Einstein and Bargmann[1] declared that "Ever since the theory of general relativity has been developed there has existed the problem of finding a unified theory of the physical field by some generalization of the relativistic theory of gravitation . . . a decisive modification of the fundamental concepts is unavoidable". Schrödinger[2] has also explained the need for a generalization of Einstein's original postulates in order to unify the theories of gravitation, electromagnetism, and the mesonic field responsible for binding the nucleus. There is no danger of the work of Einstein and Schrödinger being overlooked, but there is great danger that what is apparently an investigation of great importance, namely, "The Theory of Indeterminate Space-Time", by F. R. Saxby, may be missed by physicists, as it appears not in any of the usual scientific journals, but in the *Bulletin of the Research Laboratories of the National Cash Register Company* (pp. 13–72, September 1943), of which laboratories he is mathematics staff engineer.

Mr. Saxby proceeds on something like the general lines of the recent work of Einstein and Schrödinger, being influenced, like them, by the variations introduced into the original relativity theory by Weyl and Eddington; but his treatment has one strikingly original feature, which seems to link up quantum theory with relativity. If this claim can be substantiated, a great advance has been made. As Schrödinger[2] remarked: "At the back of our striving for a unitary field theory, the great problem awaits us of bringing it into line with quantum theory. This point is still covered with deep mist."

It is difficult to give a summary of Saxby's paper without complicated mathematics, but at any rate it can be indicated how it is related to Schrödinger's investigations. Both agree that the first step is to assume, as a postulate, that a certain correspondence exists between two vectors at two neighbouring points of space, or more generally between two *tensors* at two neighbouring points of space-time. The relation assumed is of a special form, known technically as an 'affine connexion'. It contains sixty-four arbitrary coefficients. In Einstein's original theory there were certain additional assumptions which restricted these coefficients, in particular an assumption of symmetry. Both Schrödinger and Saxby emphasize the non-symmetric case, the former to account for the meson field, the latter to account for the quantum. In both cases the gravitational part of the theory is much the same as in Einstein's older theory, but there are novelties in the electromagnetic part, particularly in Saxby's treatment, which differs radically from any previously given. It is claimed that the new theory links up the indeterminism of the electromagnetic potentials with Heisenberg's principle of uncertainty.

Mr. Saxby admits that much has yet to be done in developing his theory, and it is to be hoped that he will be able to publish an account of it in periodicals usually taken by university libraries. Einstein's own new investigations[1] go more deeply into the purely mathematical side of the correspondence between two tensors, but he says: "whether we have succeeded in approaching the solution of this physical problem [that is, that of a unified theory of physics] is still uncertain. The answer to this question depends, among other things, on a mathematical problem which we have not yet been able to solve".

## IMPERIAL FORESTRY INSTITUTE, OXFORD

THE nineteenth annual report of the Imperial Forestry Institute, Oxford, for 1942–43 is inevitably coloured by war conditions. It proves somewhat difficult for those interested but not connected with Oxford to distinguish the actual staff of the Department or School of Forestry from that of the Imperial Forestry Institute; in other words, the part of the forestry staff maintained by the University of Oxford from its own funds as compared with the grants expended upon the Institute coming from Government sources, Forestry Commission, several Colonies, and so forth.

As the report remarks, the Forestry Commission has issued a White Paper (Cmd. 6447) on future forest policy in Great Britain, which has not yet received the sanction of the House of Commons. A Supplementary Report (Cmd. 6500. London: H.M. Stationery Office, 2*d.* net), dealing with the forest policy of private woodlands, was published early in 1944. There had been controversy on the proposals in the first White Paper for the treatment of the private landowner and his woodlands (which had provided the bulk of the timber and other forest materials required for the War) and considerable opposition became apparent throughout the country. A conference was held between the Forestry Commission and representatives of landowners and forestry societies, and the reconsidered proposals agreed upon, mainly connected with the help which could be granted to private landowners towards afforesting and re-afforesting their felled-over lands, were published in the Supplementary White Paper.

The portions of the White Paper alluded to in the Imperial Forestry Institute's report are the sections on education and research, which particularly concern the Institute. It appears that during the year the Committee for Forestry at Oxford considered a report on the future policy of the Institute drawn up by a sub-committee. The report was adopted with certain modifications, "but it was considered necessary to keep it pending the expected publication

of the views and proposals of H.M. Forestry Commission on Post-War Forestry Policy in this Country". It is difficult to appreciate the reason for the above statement.

The Imperial Forestry Institute is an Empire organization, or at its inauguration was intended as such. Practically the whole of the forest wealth of the Empire is outside the British Isles and must remain so for many years to come. Research work is presumably one of the important branches of the Institute, and it would appear reasonable that closer co-operation in such work would be at least as necessary as with the Forestry Commission, which is so stressed in the report. Moreover, there are other universities with forest departments ready to undertake research work in collaboration with the Forestry Commission; but there is only one Imperial Forestry Institute, and that is situated at Oxford.

The suggestion for raising the status of the Institute from a pass to an honours school is a wise and far-sighted move.

The only students under instruction during the year were the Colonial forestry scholars, four attending the Institute, two of whom were forestry graduates. There was also one candidate for B.Sc., and one for D.Phil. working under the supervision of the professor of forestry.

# A NEW MEXICAN VOLCANO

P. D. TRASK has recently given a preliminary account of the inception and growth of a new volcano, El Paricutin, situated about two hundred miles due west of Mexico City (*Trans. New York Acad. Sci.*; Dec. 1943).

Prof. L. C. Graton, professor of mining geology at Harvard, spent nearly two months in the region making trips to it and flying over it twice; and he describes its growth in *Sky and Telescope* of February. A well-illustrated article on the volcano also appears in the *National Geographic Magazine* of February 1944.

The first intimation of awakening activity was the occurrence in February 1943 of numerous earthquakes in the district. On February 19 some three hundred shocks were reported. The next day a Tarascan Indian farmer was astonished to see 'smoke' spiralling up from a hole in a field which he was ploughing.

That night the first explosion occurred, and since then—at least up to the end of the year—the volcano has been erupting steadily. Within a week the cone reached a height of 550 ft. and by late September it had grown to 1,500 ft. During the early days explosions in quick succession expelled a cylindrical column of ash which, after reaching a height of some hundreds of feet, suddenly formed dark expanding clouds that billowed up to 6,000 – 8,000 ft., when steam began to condense, after which the ash cloud became progressively whiter until it passed into a horizontal cloud of curling puffs of vapour at about 15,000 – 18,000 ft. Later on, much of the fragmental material consisted of red-hot bombs, blown 2,000 – 3,000 ft. into the air. A cone 100 ft. high was built up in the course of the first day.

Two days after the birth of the volcano, lava emerged from a field about a quarter of a mile from the crater and continued to flow for six weeks, by which time it was more than a mile long and 100 ft. thick. Early in June eight lava flows issued from the cone itself. The crater at this time was occupied by lava to within 50 ft. of the rim, and through the congealed blocky surface ashes were being erupted. It was observed that each flow was preceded by a phase of violent explosive activity, but that while lava was actually escaping, explosions were relatively few. By September several other flows had broken through the flanks of the cone. The lava consists of andesitic basalt of essentially the same type as that erupted by the hundreds of older and now apparently extinct volcanoes that occur within a radius of about seventy-five miles around Parícutin.

It is of interest that the only previous volcanic activity in the region, within the memory of man, occurred in 1759 when the celebrated new volcano of Jorullo suddenly appeared, some fifty miles to the south-east of Parícutin, and built a 1,000-ft. cone in five months of activity.

# NATIVE RESERVES IN SOUTH AFRICA

THE Native Reserves provide homes for one third of the South African population, and constitute the chief source of labour for mines and industries. Soil wastage, resulting from over-stocking and primitive methods of agriculture, is rapidly converting the reserves into deserts. A memorandum, drawn up at the suggestion of the Cape Town Branch of the Association of Scientific Workers of Southern Africa, puts forward a comprehensive scheme of reorganization*.

A start might be made in the following terms with certain limited areas, and the new system gradually extended until it covers the entire Reserves. (1) An ecological survey of the given area; (2) the area to be fenced and made into suitable paddocks for summer and winter grazing; (3) all scrub bulls to be culled and the necessary number of good bulls to be provided; (4) progressive limitation of cattle to the estimated carrying capacity of the land. It would be a good thing to regard each area as a collective farm, and each communal farm should have a communal centre with offices, hall for meetings and lectures, perhaps a school building, barns and silos, sheds for storage, etc. An African agricultural officer, as general adviser, should be stationed at each farm. Families would be entitled to their own plots of arable land fenced off from the communal land. Though encouraged to store and market collectively, the individual peasant would be entitled to the products of his own land, and individual ownership of cattle would have to be tolerated. All able-bodied members of the *commune* would be expected to provide a minimum amount of labour under the management of a committee. Technical training schemes would also be desirable.

It is realized that certain major changes in South African governmental policy—improvement in the social and commercial conditions of Africans outside the Reserves and provision of more land and industrial opportunities within—must accompany any serious attempt to deal with the general problem.

K. L. LITTLE.

## FORTHCOMING EVENTS

### Wednesday, July 19

IRON AND STEEL INSTITUTE (joint meeting with the SHEFFIELD BRANCH OF THE INSTITUTE OF BRITISH FOUNDRYMEN) (at the Royal Victoria Station Hotel, Sheffield), at 7 p.m.—Mr. P. C. Fassotte: "Developments in the Design and Use of Side-Blown Converter Plants".

### Thursday, July 20

LONDON MATHEMATICAL SOCIETY (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 3 p.m.—Mr. G. A. Barnard: "Some Applications of Modern Higher Algebra to Engineering Statistics".

### Friday, July 21

GENETICAL SOCIETY (in the Department of Comparative Anatomy, University Museum, Parks Road, Oxford), at 12 noon—Annual Meeting.

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

DEMONSTRATOR (man or woman) IN THE DEPARTMENT OF INORGANIC AND PHYSICAL CHEMISTRY—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1 (July 17).

LECTURER IN MATHEMATICS AND PHYSICS—The Director, Robert Gordon's Technical College, Aberdeen (July 18).

TEACHER (full-time) OF MATHEMATICS, SCIENCE and DRAWING, mainly for employment in a new Junior School of Building—The Secretary, Bridgwater Art and Technical Institute, 142 Chilton Road, Bridgwater, Somerset (July 19).

EDUCATIONAL PSYCHOLOGIST (full-time) to work in the Child Guidance Clinic and in connexion with Schools and Institutions—The Director of Education, Education Offices, Deansgate, Manchester 3 (July 20).

SCIENCE MASTER or MISTRESS for the Boys' Junior Technical and Day Continuation School—The Organizer of Further Education in Rugby, College of Technology and Arts, Eastlands, Rugby (July 21).

ASSISTANT MASTER (Graduate preferred) to teach MATHEMATICS and SCIENCE, particularly CHEMISTRY—The Headmaster, Eastbourne Junior Technical School and Evening Institute, The Grange, St. Anne's Road, Eastbourne (July 22).

SUPERINTENDENT OF THE ENGINEERING DIVISION of the National Physical Laboratory—The Director, National Physical Laboratory, Teddington, Middx. (July 22).

LECTURESHIP IN CHEMISTRY—The Registrar, The University, Reading (July 24).

LECTURER IN MECHANICAL ENGINEERING—The Registrar, King's College, Newcastle-upon-Tyne (July 24).

LECTURER FOR MECHANICAL OR AERONAUTICAL ENGINEERING SUBJECTS—The Secretary, Northampton Polytechnic, St. John Street, London, E.C.1 (July 24).

LECTURER (full-time) IN PHYSICS AND MATHEMATICS in the Engineering Department of the Schools of Technology, Art and Commerce—The Chief Education Officer, City Education Office, 77 George Street, Oxford (July 24).

CHEMISTS (temporary) with considerable experience in analysis of metals—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. F.2828A) (July 25).

CHAIR OF MATHEMATICS tenable at the Royal Holloway College—The Academic Registrar, University of London, c/o Richmond College, Richmond, Surrey (July 26).

LECTURER IN EXPERIMENTAL PHYSIOLOGY—The Registrar, The University, Sheffield (July 28).

SUPERINTENDENT OF THE LIVERPOOL GAS COMPANY'S CENTRALIZED CONSTRUCTION AND WORKS MAINTENANCE DEPARTMENT—The Personnel Superintendent, 18–26 Bold Street, Liverpool 1 (July 29).

ASSISTANT SECRETARY to the Oxford and Cambridge Schools Examination Board—The Chairman of the Oxford Delegacy, St. Catherine's Building, St. Aldate's, Oxford (July 31).

ASSISTANT LECTURER IN THE DEPARTMENT OF MATHEMATICS, an ASSISTANT LECTURER (temporary) IN THE DEPARTMENT OF PHYSICS, and an ASSISTANT LECTURER (temporary) IN THE DEPARTMENT OF ENGINEERING (with special qualifications in Electrical Engineering)—The Registrar, University College, Singleton Park, Swansea (August 5).

SENIOR TECHNICAL OFFICER (temporary) at London Headquarters of the Ministry of Town and Country Planning—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. EA. 950A) (August 10).

READERSHIP IN PHYSICAL ANTHROPOLOGY—The Registrar, University Registry, Oxford (August 31).

CHAIR OF ELECTRICAL ENGINEERING—The Acting Registrar, The University, Leeds 2 (September 30).

SECRETARY—The Hon. Secretary, Illuminating Engineering Society, 32 Victoria Street, London, S.W.1.

LECTURER (full-time) IN THE SCIENCE DEPARTMENT (principal subjects: Inorganic, Organic and Physical Chemistry, with subsidiary Physics)—The Registrar, Merchant Venturers' Technical College, Bristol.

PSYCHIATRIC SOCIAL SERVICE WORKER for the Glasgow Royal Mental Hospital and associated Out-patient Clinics—The Medical Superintendent, Glasgow Royal Mental Hospital, 1055 Great Western Road, Glasgow.

GRADUATE TEACHER OF GENERAL SCIENCE OR GENERAL ENGINEERING SUBJECTS in the Burton-on-Trent Technical Institute and Junior Technical School—The Secretary and Director of Education, Education Offices, Guild Street, Burton-on-Trent.

SENIOR MASTER with good Honours Degree in Science or Mathematics, and an ASSISTANT MASTER with Degree in Science or Mathematics, in the Leeds Central High School—The Director of Education, Education Offices, Leeds 1.

ASSISTANT MASTER qualified to teach ENGINEERING SUBJECTS and MATHEMATICS up to Ordinary National Certificate standard—The Principal, Technical Institute, Beckenham Road, Beckenham, Kent.

TEACHER OF MATHEMATICS, PHYSICS AND CHEMISTRY, and a TEACHER OF MECHANICAL ENGINEERING, ELECTRICAL ENGINEERING and BUILDING—The Principal, Technical College, Bradford Place, Walsall.

LABORATORY ASSISTANT IN THE DEPARTMENT OF PHYSICS—The Bursar and Acting Registrar, University College of North Wales, Bangor.

## FUNCTIONAL APPROACH TO INTERNATIONAL CO-OPERATION

NO feature of the recent conference of Prime Ministers of the British Empire has been of wider interest than the attention given to the shaping of international organization after the War. No less impressive than the evidence of the unity of the British Commonwealth on essentials, and of its identity of spirit and resolve, is that of willingness to assume the responsibilities of world leadership and to make constructive proposals for the organization and maintenance of world peace. The emphasis placed on the inclusive rather than exclusive character of the British Empire is welcome and wise, all the more when, as in the recent speeches of Mr. Cordell Hull, of Mr. Dewey and others, there is evidence that the United States is giving equal attention to such questions. Furthermore, it is clear that some American periodicals such as *Foreign Affairs* are making a bold attempt to prepare American opinion to face whatever changes may be involved and to clear away misunderstandings that might hinder Anglo-American co-operation.

An interesting feature of recent discussions has been the tendency to reconsider the verdict on the League of Nations and to look to the reconstitution of such an organization after the War. In December 1942, Mr. Eden, for example, declared that the old League of Nations did not fail because its machinery was faulty but because there was "insufficiently representative force or drive behind it". "There are", said Mr. Eden, "three indispensable attributes for an international organization if it is to have a chance to achieve its purpose. First, it must be fully representative of the Powers that mean to keep the peace; secondly, it is for those Powers themselves to have the unity and the determination to arrive at great positive decisions; thirdly, they should have force behind them to give effect to their decisions".

Much the same line of thought has been discernible in Mr. Churchill's recent references to this question, and especially in his statement in the House of Commons on May 24; while the picture of international organization which General Smuts gave in his broadcast to the United States last December closely resembles in structure the old League of Nations. Within the wider democratic organization of the United Nations, he said, there would be not only a council and an assembly on the existing League of Nations model, but also a definite responsibility on the four great Powers, the United States, the British Commonwealth of Nations, the U.S.S.R. and China, for maintaining peace, at least while the new world organization is being built up. National sovereignty would be respected, but there would be an international regime of law and order which would guarantee to each State a peaceful life of its own, and the aggressor would be dealt with by international authority as an outlaw.

General Smuts firmly rejected the current criticism in the United States that the League of Nations asked too much of its members. He argued that the contrary is true. The obligations imposed by the League

were too indefinite and too slight, and insufficient provision was made for the supply of force. In effect, he accepts the argument consistently used by the French, and supported by several minor European Powers, although opposed by Britain, the United States and Germany.

General Smuts hopes that under the leadership of the four great Powers there will be built a habit of co-operation in the critical years immediately following the War, and that it will become a real basis of future security. In this way would be remedied the lack of will which first wrought the mischief twenty years ago. The question of sovereignty is handled very delicately, but nowhere does he quite put the real issue so plainly as Mr. Wilkie in a recent article, when he urged that the best way for the United States—and other nations—to preserve its sovereignty is to exercise it as part of a world pattern of co-operation.

It will be noted again that General Smuts passed lightly over the common tasks of the new organization outside its police work. Of its economic functions he said little, nor did he touch on the functional proposals which represent one important approach to the organization of peace and are not necessarily inconsistent with his own outline. Nothing in his defence of the old League or in his proposals for a new one holds any support for indulgence by the British Commonwealth once more in an easy peace, which far more than any shortcomings, political or economic, in the Versailles Treaty was our undoing.

That is indeed one of the surest grounds for hope. While the structure of a new world organization is only tentatively outlined, in Great Britain as in America, public opinion is being educated to what is involved and prepared for the demands that must be made upon it for the support of any system of security. Recognition that any structure of peace must be backed by adequate force must be followed by the recognition that adequate force involves the support of adequate measures and policies to provide that force, and a break once for all with the fatal habit of the inter-war years of enunciating principles and proclaiming policies without assuring the means of making them effective.

That means in practice that some joint strategy common to the members of the British Commonwealth and to the other great countries of the United Nations must be planned, and preparations made to put it into execution. Such joint effect should develop the essential habits of co-operation and in time create appropriate organs adapted to the functions they are called upon to perform. Defence, in fact, is only another functional approach to the main problem, and as in so many other fields the most promising line of advance lies in the adaptation to our post-war purposes of the machinery called into being by the dire exigencies of war.

The functional approach to the problem of the organization of world order is not the only way in which new arrangements for international co-operation are already being evolved. The regional approach as exemplified in the Anglo-American Caribbean Commission or the Middle East Supply Centre is fully as important as the functional developments represented by the interim Commission on Food and Agriculture resulting from the Hot Springs Conference, and also the United Nations Relief and Rehabilitation Administration. Both types are consistent with the structure outlined by General Smuts and with the seventeen points of the basic statement on foreign policy of the United States issued by Mr. Cordell Hull in April.

That such proposals do not as yet include any definite provision for either the continuation of the League of Nations as a body entrusted with the co-ordination of the activities of a number of international bodies, or the creation of a new international organization entrusted with such functions, does not warrant any hasty conclusions that what is useful in existing organizations will not be incorporated in a new or remodelled organization. Always provided that the fundamental thought and examination are proceeding, it is no bad thing that time should be taken to formulate proposals for the ultimate structure of the permanent world organization to give effect to the points of the Atlantic Charter and subsequent declarations of the United Nations. The growth of a sense of common purposes and ideals and fellowship which is one of the invaluable results of functional organizations is always a slow process, and on this point Mr. M. R. C. Greaves' "The League Committees and World Order" will richly repay further study.

Uneasiness on this point, which is betrayed both in the long report on "The Future Policy, Programme and Status of the International Labour Organization" prepared for discussion at the Philadelphia Conference, and in the Report on the Work of the League of Nations, 1942–43, submitted by the Acting Secretary-General, may well be unfounded. The International Labour Organisation, it is true, has had to establish with each of the new bodies as it is created working relationships equivalent to those which, during the inter-war period, covered a wide field of international co-operation. Nevertheless, it may well be that the distinctive contribution of the International Labour Organisation to the strengthening of the whole structure of international organization now being evolved may best be made, in virture of its tripartite composition, if the Organisation conceives of its activities on functional lines, and pursues policies and activities in accordance therewith. The Organisation possesses no executive authority, and to press too far into such fields as that of full employment, which call for the exercise of authority in economic matters, may well be detrimental rather than beneficial to its influence.

The creation of functional international bodies for handling world social and economic problems is not an end in itself, but a step towards the achievement of a larger objective. Whatever functional bodies may be established will require effective co-ordination in a general pattern of international economic organization, and this general pattern in turn must be integrated appropriately with the general international organization for the maintenance of inter-

national peace and security contemplated by the Moscow declaration. This point is rightly emphasized in the report on the future of the International Labour Organisation already mentioned, which points out that it may be reasonably assumed that the constitutions of the functional bodies which are being created will be framed so as to allow effective co-ordination of their activities and the ultimate attainment of the larger objective of a comprehensive and integrated structure of world institutions. Failure to achieve such co-ordination must in fact seriously prejudice the efficient operation of such bodies.

While agreeing that a close and organic relationship must be established between the International Labour Organisation and the general international organization of the future, it is urged that the contribution of the International Labour Organisation to the co-ordination of international public policy must be made in a manner which does not involve renunciation of its tradition of constitutional autonomy, which has contributed much to the vitality of the Organisation and is a major safeguard for its capacity to weather future storms. At the same time, the Organisation is itself potentially an instrument through which there can be achieved both a measure of co-ordination of the specialized agencies now being envisaged and an adequate backing from public opinion for their work. Co-ordination of the different fields of international public policy requires, it must be remembered, not only machinery for taking immediate decisions but also machinery for the general exchange of views on objectives and methods of approach. For the fulfilment of this second function the International Labour Conference appears to be a uniquely appropriate instrument, and its experience may well prove invaluable in working out the precise machinery by which expression is to be given to the democratic ideal in the progress towards world government.

The introduction to the Acting Secretary-General's report on the work of the League makes another useful contribution to this discussion of the future world organization. Its summary of representative views shows that the fundamental ideas on which public pronouncements concur are not greatly dissimilar from the principles of the Covenant of the League of Nations, and that certain general principles are gaining recognition. These principles must be accepted as the bases of continuous co-operation and embodied in definite undertakings. There must clearly be a permanent organization, and whether or not the League of Nations itself is reconstituted we should avail ourselves of its experience over a period of twenty years.

The Acting Secretary-General in his report suggests as a useful method of approach the careful examination of the provisions of the Covenant, to determine for each the principle its authors wished to establish and to ascertain whether that principle can now be considered as generally acceptable. If so, past experience should show whether the means provided in the Covenant to give practical application of the principle are sufficient, and whether it was the power and the will to apply them that were lacking.

One of the problems that will require reconsideration in the light of the lessons of the War is that of joint military action. This is one of the novel features of the plan for world settlement outlined by Ely Culbertson in his "Summary of the World Federation Plan"* of which a more detailed account has since been published in the United States under the title "Total Peace". Mr. Culbertson dismisses as fallacy the idea of reviving the League of Nations, although he regards its work as laying the foundations for a new attempt at world order. Mr. Street's plan for Federal Union is also dismissed as premature in the face of the dominant force of nationalism. Co-operation of sovereign nations must precede world federation of nations and the world parliament of man. Neither of these plans takes into full account the revolutionary changes in science, military weapons, communications and economics of our generation; but Mr. Culbertson's "Summary" does not specify the fatal defects of structure which in his view crippled the League of Nations from the start, and the real defect in the Federal Union proposals is probably one of rigidity rather than of timing.

Meanwhile, the League report itself recognizes that structural defects may hamper the development of an institution, however much we agree with Mr. C. J. Hambro that organic growth in itself can never be made to conform to blue-prints but creates constantly new problems. Moreover, if the means placed at the disposal of an international institution are not commensurate with the aim in view, the loftier the aim the greater the risk that the institution may sooner or later meet with a serious failure, which will shake confidence and make reconstruction difficult. Nevertheless, there is some substance in the suggestion of this League report that what is sometimes regarded as the liability of the old name might prove an asset for the new attempt to establish world order, because use of the old name should discourage any tendency to think that the machine of itself would produce results, whereas they can only come from consistent effort and loyalty and goodwill.

Mr. Culbertson, however, is at one with the League report in holding that the future world organization cannot be left over entirely until peace and order have been re-established. The details may be left, as Mr. Churchill has suggested, to be settled after the formidable foes we are now facing have been beaten down and reduced to complete submission. This view was afterwards endorsed by Mr. Eden, who suggested, as one of the five principles on which world organization should be based, flexibility and growth by practice without attempting to work to a fixed and rigid code or rule; but a prior and clear-cut decision as to the revival of the collective security system and guaranteed mutual help might well aid in solving many thorny problems, such as those relating to frontiers.

Mr. Churchill, in his review of foreign policy on May 24, contemplated a world order and organization equipped with all the necessary power to prevent

* Summary of the World Federation Plan: an Outline of a Practical and Detailed Plan for World Settlement. By Ely Culbertson. Pp. 78. (London: Faber and Faber, Ltd., 1944.) 5s. net.

future wars or the planning of them in advance by restless and ambitious nations. That organization would include a world council of the greatest States for the purpose of preventing war, as well as a world assembly of all Powers. Mr. Churchill would not commit himself to the precise relations of these bodies or to the question of united forces of nations as against world police for keeping the peace. He considered that we should undoubtedly embody in our world structure a great part of all that had been gained for the world by the structure and formation of the League of Nations, but within the limits assigned to it we must make sure that our world organization has overwhelming military power. These points were later elaborated by Mr. Eden as three of four principles of world organization, the fifth being that the Powers included should strive for economic as well as for political collaboration.

That is the main purpose of Mr. Culbertson's quota force principle. This is a new system of composition and distribution of national armed forces, based on heavy weapons. The world police, under this system, would be the only force in the world which is armed with heavy weapons (that is, armoured aeroplanes, capital ships, tanks and heavy guns), the manufacture, transportation and possession of which would be the monopoly of the world federation. This police force would consist of twelve separate armies: eleven national contingents recruited from the citizens of each initiating State, and an international contingent, called the mobile corps, of units or regiments, or their naval and air equivalents, recruited from all member States other than the initiating States, and distributed, in contrast to the national contingents, which will be stationed only in their country of origin, only in strategically located islands purchased by the Government of the World Federation and in leased bases in States which participate in two regions. Quotas assigned to the national contingent are based on the industrial power of the initiating State, the extent of the regional territory it must defend and on the psycho-political factor. The international mobile corps would be stronger than the strongest contingent of any initiating State.

This scheme for a double military system is ingenious, and while some points of detail such as the relative allotment of power as between the U.S.S.R., the United States and the British Commonwealth may be hard to justify, it at least merits serious consideration, and represents something which might well develop naturally from the position in which the United Nations will find themselves after the War. It is certainly not inconsistent with the picture of world organization sketched by General Smuts or by Mr. Churchill. For the rest, it may be said that Mr. Culbertson's plan is based on a regional system, the arguments for which are given in his book, "Total Peace"; this may explain some of the inconsistencies which appear to characterize the plan as presented here. Its fundamental assumptions no less than its specific objects are common ground in most discussions to-day on the form of world organization. The substance of them is to be found in the speeches of Mr. Churchill and of Mr. Eden on May 24 and 25. Mr. Culbertson himself, for example, in furtherance of the establishment of world-wide educational, scientific and economic institutions, would embody within the world federation the present agencies which the United Nations, the League of Nations and the larger peace foundations have already established for these ends.

If on the evidence so far presented some of the details of Mr. Culbertson's plan are not entirely convincing, in spite of the serious study which his suggestion for a double military system deserves, to that extent they attest the wisdom of Mr. Churchill's warning against putting forward formally and in too great detail our own views or solutions in a manner which might prejudice their consideration. The importance of democratic procedure in establishing a permanent organization is sometimes overlooked, but without it the consent of all participating nations is not likely to be easily won or held. Nevertheless, though methods and details may vary, through all these proposals, from whatever source, runs the common thread that, as Mr. Eden said in concluding his speech, only by translating into the period of peace the confidence we have built up among our allies in war can we hope to save the world from a repetition of these conflicts. Given the will, courage and elasticity of mind, firmness of purpose, the ability to learn from the past, to adapt to our present and future needs whatever of value existing institutions may hold, there is no room for pessimism. The constructive thought and imagination displayed in these and other speeches and papers show that mankind is capable of providing himself with the institutions necessary to ensure that the fruits of victory are enjoyed, and that the great heritage of civilization, the rights and liberties of individuals, are not again endangered by nationalistic ambitions.

## A SURVEY OF THE UNIVERSE

### The Universe Around Us

By Sir James Jeans. Fourth edition, revised and reset. Pp. x+297+32 plates. (Cambridge: At the Oxford University Press, 1944.) 15*s*. net.

IN the decade that has elapsed since the third edition of this well-known book, many advances in astronomy have been made. Sir James Jeans has incorporated reference to many of these in the new edition, and has taken the opportunity to make a thorough revision and to rewrite a large part of the book. Thus, for example, reference is made to the recent discovery of companions of small mass belonging to the systems of 61 Cygni and 70 Ophiuchi; some account is given of Eddington's investigations on the expansion of the universe and the rate of recession of the extra-galactic nebulæ; and the bearing of the new knowledge of the source of stellar energy, derived from the study of thermo-nuclear reactions, on the evolution of the stars is described.

Thus the book continues to provide one of the best accounts available in simple language of the results of modern astronomical research. A very wide field is covered, for an account of modern

atomic and quantum theory is included; this is a great help to the general reader. The book is written with Sir James Jeans's usual clarity of style and facility of expression. It abounds in apt and striking illustrations and analogies; to give but one example, the statement that the temperature at the centre of a star is about twenty million degrees conveys little to the average reader, but the remark that a pin-head of matter at that temperature would emit enough heat to kill anyone who ventured within a hundred miles of it helps the reader to realize something of what such a temperature involves.

There are a few places where a little further explanation would have been helpful to the lay reader. Thus, on p. 33 it is stated that "in 1814 Fraunhofer repeated Newton's analysis of sunlight, and found that the spectrum was crossed by a number of dark lines"; a reader who knows nothing about the spectroscope but is familiar with Newton's experiment, in which a coloured band was formed by overlapping images of the sun, may be left wondering why the spectrum is crossed by *lines*. On p. 65, it is stated that the rotation of the galaxy makes it difficult to believe in a local cluster of stars, because such a cluster could not be a permanent structure; the reader may object that some of the photographs of extra-galactic nebulæ appear to show many such local clusterings.

On pp. 25, 26 it is said that Ptolemy argued that the earth could not be moving through space because this would involve a displacement of the nearer stars relative to the background of more distant stars; this is misleading, because in Ptolemy's time and for many centuries after, it was believed that the stars were all fixed to a sphere. A motion of the earth would have involved changes in the angular separations of the stars, of the nature of proper-motions, and it was through displacements of this type that William Herschel was enabled to detect the motion of the sun relative to the stars.

On p. 204, referring to the hydrogen content of the stars, it should be mentioned whether the stated percentage is by mass or by volume. The statement on p. 253 that the swarm of asteroids can be explained *quite simply* as the broken fragments of a primeval planet is not correct, if it is meant to imply that it has been proved that the asteroids originated in this manner. Nor is the statement that there are several families of comets the members of which follow one another round and round in the same orbit (p. 256) correct. The explanation of comets as part of the *débris* left after the birth of the planets shelves the difficult question of the origin of comets; several comets have been observed to disrupt, and traces of them can be detected by showers of shooting stars when the earth meets the orbit of the disrupted comet; there is no evidence of any comet having entered the solar system from outside; it seems that the formation of comets must be a continuing process in the solar system, though there is no satisfactory theory to account for this.

But these are minor defects in a book of absorbing interest, which carries the reader through space and time, discusses the evolution of the stars and of the universe, and concludes with a fascinating chapter on beginnings and endings. The black-out conditions during the War have enabled many people to see the glory of the heavens for the first time, and this has brought about a greatly increased interest in astronomy. This book should do much to stimulate that interest.

H. SPENCER JONES.

# ELEMENTARY WAVE MECHANICS

## Elementary Wave Mechanics

Introductory Course of Lectures. By W. Heitler. Notes taken and prepared by W. S. E. Hickson. (Hectographed.) Pp. ii+88. (Dublin: Dublin Institute for Advanced Studies, 1943.) 5*s*.

THERE are many elementary treatises on wave mechanics. Their multiplicity is due perhaps to the fact that there are many ways of approach to this subject or perhaps because, as in the case of a disease for which many cures are advertised, the right treatment still awaits discovery.

The present work is based on notes taken on a course of lectures given by the author. It contains features which distinguish it from similar works and which make its publication well worth while.

It is clearly the work of a lucid teacher, and this is to be expected of the author of "The Quantum Theory of Radiation". It is the work of a writer who can keep the physical principles of the subject in the foreground and at the same time introduce the reader to the essentials of the mathematical technique, with some pardonable short cuts.

The book covers a representative range of problems, including the treatment of the hydrogen-like atoms and the problem of two electrons. Welcome additional subjects of study in a work of this scope are the perturbation theory, exchange degeneracy, the spin wave function and the helium atom.

The uncertainty relations are presented in a way which is likely to lead the student to think of them as peculiar to the quantum theory. The sense in which this is true is stated by the author (p. 13), where he writes: "Classical mechanics holds for heavy bodies, the uncertainties are a peculiarity of quantum mechanics which applies to light particles". It is, however, advisable that the student should be aware of Rayleigh's conditions of optical instruments, some simple examples of which can be explained from his knowledge of physical optics. This line of approach has some justification in the history of the development of the uncertainty relations and avoids the tendency towards over-emphasis upon the application in wave mechanics.

It is to be regretted that the wave-length of the particle waves is described as being inversely proportional to the particle velocity although this is true in the limited application considered. It is preferable to describe the wave-length as inversely proportional to the momentum, since this is a true statement both in the classical and relativistic cases.

The author attempts to lead the reader very gently to the idea that the particle velocity has its counterpart in the group velocity and not in the phase velocity of the waves. The attempt seems rather laboured and leads to the strange result that the phase velocity is half the group velocity. This may lead to confusion later on when the question has to be further considered.

The work is to be recommended to degree students who require a clear statement of the principles of the subject and a knowledge of how they are applied in practice. The syllabus chosen is excellent and affords a useful guide to teachers of the subject.

With the correction of some misprints and amplifications here and there, the work will become a valuable introductory text-book.

H. T. FLINT.

## Catalogue of Union Periodicals

Vol. 1: Science and Technology. Edited for the National Research Council and National Research Board by Percy Freer. Pp. xvi+525. (Johannesburg: University of the Witwatersrand, 1943.)

THIS catalogue covers the periodicals of seventy-seven libraries in the Union of South Africa which have agreed to co-operate in inter-library loaning. While it should primarily facilitate such loans and thus materially aid the war effort in South Africa, it is also an important aid to reshuffling so as to place the most complete sets in the larger centres. The catalogue renders comparatively easy the compilation of a national list of desiderata of those important titles of which no sets or only poor sets exist in any South African library, and besides eliminating unnecessary duplication it should encourage co-operative purchase to fill the lacunæ thus revealed.

The catalogue includes many titles which are too recent to be included in the World List of Scientific Periodicals, and for that reason and also on account of the subject classification it may be found a useful guide to the existence of scientific and technical periodicals, although not for loan purposes, by scientific and technical librarians in Great Britain.

The present catalogue contains more than 6,000 entries as against 3,117 in A. C. G. Lloyd's List of 1927. The abbreviations used in the World List of Scientific Periodicals are used wherever possible and emphasized by underlining. The primary arrangement is by subject, and the sub-arrangement first by language, and second by country. Where no subject is expressed the main entry goes to the name, for example, Carnegie, Faraday, Franklin, Smithsonian, with cross-references from institutes and societies. Other main entries are under distinctive titles, while where no subject is expressed with academies, institutes or societies the main entry goes elsewhere, for example, to institutes, laboratories, museums, etc. Entries closed on September 30, 1941, and participating libraries are now invited to maintain a list of additions and corrections for quarterly publication in South African libraries.

## The Weather

By George Kimble and Raymond Bush. (Pelican Books, A.124.) Pp. 188+24 plates. (Harmondsworth and New York: Penguin Books, Ltd., 1943.) 9*d*. net.

## Meteorology

By Lieut.-Colonel R. M. Lester. (Complete Air Training Course, No. 4.) Pp. 64+4 plates. (London, New York and Melbourne: Hutchinson's Scientific and Technical Publications, n.d.) 2*s*. 6*d*. net.

"THE WEATHER", by Kimble and Bush, must be one of the best nine-pennyworths extant. It is chatty and inconsequential, but when one comes to the end and looks through the index, one realizes that it holds a great deal of solid information; even the reader who follows the suggestion to skip the introduction will miss a great deal. The structure of the atmosphere, instruments, clouds as weather forecasters, depressions and anticyclones are all dealt with simply but effectively; then follow the seasons, 'one-man' forecasting and some oddments like weather cycles, all illustrated by many rhymes from folk-lore, some clear diagrams, and twenty-four excellent cloud photographs. There are one or two errors, such as that a halo grows in diameter as the cloud lowers, but on the whole, readers—and we hope they will be many—will obtain a very good grounding in meteorology.

Lieut.-Colonel Lester's little book is chiefly remarkable for its surprising statements. Its quality may best be shown by a few quotations: "No two snow crystals are ever alike. When one considers the millions of crystals that fall in a snow-storm, this is an amazing feat of nature." "Rainfall is greater at high altitudes. This is caused by the air coming into contact with the cold surfaces of these higher regions." Cyclostrophic effect in wind. "This is the deviation of its flow further from the curved path through the gyroscopic properties of the air mass." "A satisfactory type of rainfall gauge is a brass tube of just over two inches diameter inside an eight-inch cylindrical can."

C. E. P. BROOKS.

## Quantitative Chemical Analysis

A Student's Handbook. By Prof. Joseph Reilly and Eileen A. Moynihan. Pp. x+116. (Cork: Cork University Press, 1944.) 7*s*. 6*d*.

THIS is a very carefully written and good introduction to quantitative analysis by teachers who have evidently had much experience in presenting the subject to students, and have the ability to write a clear and concise account of all the details of the laboratory work which are essential to success. It includes both volumetric and gravimetric analysis, and the examples chosen are very good. The main emphasis is practical; the chief fault of many books, that of writing an elementary treatise on physical chemistry interspersed with a few practical exercises which are generally quite inadequately described, is avoided. The relevant theory is always given, but in its proper proportion, and the result is a very good practical manual which will make easier the work of teachers who adopt it.

The standard of the book is between the intermediate and final of most university degree courses. An appendix describes a method of phosphate separation in qualitative analysis by means of zirconium oxychloride which is an improvement on the usual procedure by this method.

## Martindale's The Extra Pharmacopoeia

Twenty-second edition. In 2 vols. Vol. 2. Pp. xxxiii+1217. 27*s*. 6*d*. Supplement to Vol. 1. Pp. 48. 2*s*. (London: The Pharmaceutical Press, 1943.)

THE second volume of Martindale continues to provide modern and reliable information on drugs and their assay, biochemistry, bacteriology, nutrition and therapy in general. The material provided is as up to date as is compatible with the time necessary to compile and produce the book. The sulphonamides and the vitamins, on which much recent work has been done, are well documented, but the short notes on penicillin direct attention to the rapidity of progress in this field.

As a book of reference for the clinician, pharmacologist and research worker "Martindale" is already well established, and the new volume will deserve the reputation of its predecessors.

The supplement to Volume 1 records changes in, and additions to, the British and United States Pharmacopoeias and National Formularies. There are also notes on recent Orders affecting supplies of drugs, new proprietary names and approved names of substances.

# JOHN DALTON, 1766–1844

By DR. J. NEWTON FRIEND
Central Technical College, Birmingham

ON July 27, 1844, at the ripe age of seventy-eight, John Dalton passed peacefully away in Manchester. Local feeling was stirred to its depths; it was unanimously agreed that nothing less than a public funeral could express the reverence felt for the memory of so great a man. This was the more remarkable since Dalton was a strict Quaker and as such was opposed to official ceremony. His remains lay in the darkened town hall, where some 40,000 people paid homage before interment took place in Ardwick Cemetery on August 12.

So many biographies and sketches of the life of Dalton have been published from time to time that it would be superfluous to labour the details in these columns. Suffice it to say that Dalton was born, probably on September 5, 1766, of humble parents in a thatched cottage in the secluded Cumberland hamlet of Eaglesfield, some half a dozen miles from Cockermouth. The cottage still stands, the thatch replaced by slate, and a suitably inscribed commemorative tablet has been inserted above the door. Fig. 1 shows the cottage with the tablet. Fig. 2 shows the Friends' Meeting House at Eaglesfield (where Dalton worshipped) as it appeared in 1895. In the foreground stands Mr. Norman, the oldest inhabitant of the village and the only one who then remembered seeing Dalton.

At an early age Dalton showed unusual industry and talent; when a mere lad of twelve, he began to teach the village school in a barn, but discipline was difficult as his pupils included boys and girls several years older than himself and far more interested in each other than in their lessons. Three years later (1781) he joined his brother as usher in the Friends' School, Stramongate, Kendall, run by his cousin George Bewley. The school had been founded in 1698 and continued until some fifteen years ago, when it was closed down. It is still an educational institution, being used in part as an elementary school for senior boys and in part as school and dental clinics*.

Dalton appears to have been but an indifferent teacher, too much absorbed in his scientific pursuits to worry unduly about the progress of his pupils. About this time he gave a few lectures also to adult audiences, but Dr. Henry states that he was never an attractive lecturer. He seemed unable to devise really impressive experiments, and failed as often as he succeeded in carrying out even such elementary experiments as he did attempt. Nature seldom puts all her eggs in one basket.

While at Kendall, Dalton discovered that his idea of colour was abnormal—he was colour blind. To him pink appeared as blue, and a waggish friend suggested that this might be the cause of his remaining a bachelor, the pink cheeks of a maiden giving him "the blues".

* I am indebted to the Town Clerk of Kendall for this information.

In 1793 Dalton went to Manchester, where he entered upon a period of great scientific activity. It was here that, in 1803, he announced his Atomic Theory, which revolutionized our outlook on chemistry, rapidly raised him to the pinnacle of fame and earned for him the title of 'father of modern chemistry'. Honours of various kinds were showered upon him, but none affected his rugged character or his genuine native simplicity. In the words of Millington, one of his biographers, "even after all his triumphs and scientific achievements, he was at heart the simple countryman of frugal tastes, speaking the broad dialect of the Cumberland fells".

Dalton's interests, however, were by no means confined to physics and chemistry. In 1844, having been a member of the Manchester Literary and Philosophical Society for fifty years and occupied the presidential chair for the last twenty-seven of these, he presented his fiftieth annual meteorological report, having then made more than 200,000 separate recordings. He once (1801) wrote a book on English grammar. In this he pointed out that, while logically there can only be two tenses, past and future, it is convenient to regard the immediate past and future as the present. In his treatment of gender he was less fortunate; few will accept his dictum that "phenomena" is the feminine version of "phenomenon".

FIG. 1.

In 1804 Davy invited him to lecture at the Royal Institution. Dalton evidently thought highly of Davy, referring to him as "a very agreeable and intelligent young man", but added that his habits were marred by one serious defect, to wit, he did not smoke! Six years later, Davy suggested that Dalton should offer himself as a candidate for election to the Royal Society, but Dalton did not do so, possibly because the fees were too high for one holding so meagre a purse. He never laid himself out to make money; for him money was merely a means to an end; otherwise he had no use for it. Thus in 1818 he was invited to join the Arctic Expedition of Sir John Ross at a salary of £400–£500 a year. This would have been nothing less than a fortune to Dalton; nevertheless he declined on the ground that he did not wish to interrupt his scientific investigations.

FIG. 2.

In 1822, however, Dalton was elected a fellow of the Royal Society; he also visited Paris, making the acquaintance of Laplace, Thenard, Ampère, Berthollet, Gay Lussac and numerous other savants. Alas, he could not meet Lavoisier. Ten years later he received the degree of D.C.L. at Oxford, along with his famous contemporary Faraday. In 1833 effect was given to a proposal of Charles Babbage, of calculating-machine fame, and he was awarded a Civil List pension of £150 a year, afterwards raised to £300. Meanwhile, Manchester decided to erect a statue in his honour, and that was duly completed. It still stands in the entrance to the Manchester Town Hall. In the same building is a mural painting by Ford Madox Brown depicting Dalton collecting marsh gas for his analyses. In 1834 Edinburgh conferred on him the degree of LL.D. and in the same year he was presented at Court to King William.

In a codicil to his will, Dalton bequeathed all his chemical and philosophical apparatus to his pupil and friend, Dr. William Charles Henry, who in 1854 published his well-known "Memoirs of the Life and Scientific Research of John Dalton".

Turning now to the theory which has made Dalton famous for all time, it may be well to remind ourselves that Dalton was not, and never claimed to be, the first to postulate an atomic theory of matter. Early Hindu literature shows that such a theory existed so long ago as 1200 B.C. Matter was regarded as an aggregation of minute, discrete particles which, though separated from each other by empty space, contrived to attract one another with sufficient force to account for the ordinary phenomena of cohesion. In later years the Greeks held similar views; we do not know if they borrowed them from the Hindus or arrived at them independently; they did, however, go a little further in that they regarded the particles as indestructible and always in motion. Democritus (460–360 B.C.) was an early exponent of these ideas, which at first were by no means popular but later came to be generally accepted.

Although useful to the physicist, the theory did not offer much help to the chemist, largely because it was purely qualitative in character. In the fourteenth century, Al Jildaki (died 1360) observed that "when substances react they do so by definite weights". Had this quantitative conception been suitably linked up with the atomic theory, our Law of Equivalent or Combining Weights would have been anticipated by several centuries. But the time was not ripe and the observation appears to have been forgotten. It required a Dalton to bridge the gulf.

Dalton's Atomic Theory is usually summarized as follows:

(1) The atoms of any one element are all alike and possess a definite and characteristic mass. They differ from the atoms of any other element both in their physical and chemical properties.

(2) Chemical compounds are formed when the atoms of two or more elements unite in simple chemical proportions.

Once these postulates are accepted, the Laws of Definite Proportions, Multiple Proportions and of Equivalent Weights become self-evident.

The exact manner in which Dalton arrived at his theory has been a matter of dispute, into which we need not enter. It may well be that the idea gradually crystallized in his mind as the result of prolonged thought in various directions. Neither need we worry because we now know that the theory, as given above, is not correct in detail. Thus, owing to the existence of isotopy, the atoms of any one element are not of necessity all alike; also, atoms do not always unite in simple numerical proportions when compounds are formed, as witness albumen and gelatin, to which reference is made below. The important point is that the essential feature of the theory is correct. It would not be difficult to re-state it, if such procedure were deemed necessary, to harmonize more closely with modern conceptions of matter. But a theory need not be correct in detail in order to be useful, and it is mainly by its use that we judge it.

One immediate advantage of the theory lay in the possibility it afforded of designing formulæ capable of indicating both qualitatively and quantitatively not merely the composition but also the constitution of chemical entities by means of symbols and formulæ. Hitherto, symbols had been used by the alchemists, more or less as cryptic labels, to denote various substances. Thus a circle denoted gold, a wavy line represented water, and so on. But such symbols gave no indication whatever either of the quantities involved or of the composition of the substances. Dalton denoted atoms by circles, suitably modified to distinguish between different elements. Thus ●○ represented a molecule* of carbon monoxide. As each circle denoted one atom of carbon and oxygen respectively, the formula clearly gave the amount of the gas present and its composition. When several atoms are united in a molecule, it may be possible to arrange them in different ways, yielding compounds with different properties. It is not generally known that Dalton himself realized this. He believed it to be the case with albumen and gelatin, which he formulated as

albumen gelatin

(that is, $C_2H_2ON$).

* We are ignoring the fact that at first Dalton wrote oxygen as ⊙ and afterwards altered it to ○; also that he used the word atom very frequently where we to-day would write molecule.

The example was unfortunate, for these molecules are far more complex than Dalton realized. This fact, coupled with the introduction of the simpler Berzelian notation, which led to the writing of empirical formulæ, such as $CO_2$ instead of the structural ○●○ (or OCO), caused Dalton's observation to be overlooked. Consequently when later chemists discovered true examples of isomerism, Dalton's contribution had been forgotten.

The question now arose as to how the union of atoms could take place. The first suggestion that atoms possess mechanical hooks was very natural at the time but was soon found inadequate. The connexion between chemical combination and electrical forces was then just beginning to be realized, for Nicholson and Carlisle had already in 1800 decomposed water electrically. In his Bakerian Lecture to the Royal Society in 1806, Davy formulated a qualitative electrochemical theory of chemical combination which was improved upon by Berzelius in 1812; but curiously enough, attention was focused more on the combining power of groups of atoms (radicals) than on individual atoms themselves. It was not until eight years after the passing of Dalton that Frankland introduced the conception of an atomic attractive power, that is, valency. The gate was thus opened to an enormous field of research on atomic forces and molecular structure, the confines of which even now appear to recede, like the end of a rainbow, the further we progress.

The foregoing may be regarded as some of the more immediate consequences of Dalton's theory. But the tale is not complete even yet. The atomic theory has migrated into realms undreamed of by its creator, and has opened up avenues of approach to problems the immensities of which appear to grow with each succeeding age.

In his brilliant researches, Faraday showed that electrically charged atoms or groups of atoms can exist in solution; he called them 'ions' and in 1835 enunciated his Laws of Electrolysis. It was inevitable, therefore, that the atomic conception of matter should eventually be extended also to electricity. This was first clearly done by Johnstone Stoney in 1874, who named the 'atom' of electricity an electron, and pointed out that $Ne$ is Faraday's ionic charge for a univalent ion, $N$ being Avogadro's number and $e$ the 'atom of electricity', that is, the electronic charge.

But if electricity is atomic, what about other forms of energy? The breakdown of classical methods of calculating the intensity of radiation of a black body at various temperatures led Planck in 1900 to extend the atomic idea to energy in general. He suggested that bodies can only emit radiation in discrete portions or quanta—atoms of energy. This enabled him to draw up an expression that would account completely for the observed distribution of energy in the temperature-radiation spectrum. He was also able to explain the lack of agreement between the classical formulæ of Wien and Rayleigh, and to show that these formulæ represent extreme cases of his own universal expression.

Five years later, Einstein explained photo-electric effects as due to 'atoms of light' or photons; in other words, light waves possess atomic characteristics.

Limitations of space forbid further discussion of these themes. Sufficient has been said, however, to show that Dalton's Atomic Theory has proved one of the most fertile ever propounded. Just as a crystal dropped into a solution may yield a vast crop of crystals entirely unrelated in quantity to the size of the original crystal, so Dalton's theory has been a nucleus around which have collected, and are still collecting, new laws, hypotheses and theories.

# MEN AND SCIENCE IN THE SEA FISHERIES*

By MICHAEL GRAHAM

In 1863–65, Huxley, as a member of a Royal Commission, on fisheries, made a tour; and I cannot do better than quote a report in his own words on one of the places visited—the Isle of Skye. "He would mention an occurrence which made an indelible impression on his mind—the total earnings of one of those peasants, he might say his whole property and everything belonging to him, would not come to more than £5. Certain interested parties in Glasgow . . . had got a law smuggled through the House of Commons, where nobody cared anything about it, by which it was made penal to catch a herring during the three summer months of the year, a time at which herrings were swarming in innumerable millions . . . that meant that [a man] might be totally ruined or might be put in prison for doing this. . . . Now there was not the smallest imaginable reason why that enactment should have been passed. It was a stupid, mischievous and utterly useless thing. . . . That appeared to be one of the worst forms of modern oppression."

I cannot find words to express my admiration for this passage, of which I have given only excerpts. There the man of science, quite sure of his ground, raised his voice against arrangements that were not based on scientific facts; and in this cause he used all the power of the English language to convey meaning and feeling. Reading it to-day has a reviving effect, by contrast with the polysyllabic jargon of good intention, among which so many of our modern aims meander, and are lost.

This visit of Huxley's led to the Act of 1868, by which most of the restrictions on fishing were abolished; and it set the policy of no restriction without scientific justification which has ruled Britain ever since, and affected millions of lives and fortunes. Such is the power of the scientific attitude, in a bold and able man.

A second notable event in the history of British fisheries was an International Fisheries Exhibition and Congress in 1883, presided over by Huxley, who was now president of the Royal Society. The exhibits included a very good one from the United States Bureau of Fisheries, which was at that time pre-eminent in knowledge of life in the sea, owing to the inspiration of Agassiz. This exhibit aroused great interest among British scientific men, of whom Ray Lankester was one, and it led to their signing a memorial calling for organized marine research in Britain. Their feeling formed one of the major trends at the Exhibition.

A second noticeable trend, closely connected, was the demand from Mr. James Alward, and from other good skippers, for research into the biology of the fish themselves; and a third trend, voiced by the

* Substance of a discourse delivered at the Royal Institution on June 9.

fishermen and by the younger men of science, was one of contention with Huxley and the Civil servants on the fundamental problem. Huxley said: "Nothing that we do seriously affects the number of fish. And any attempt to regulate these fisheries seems consequently, from the nature of the case, to be useless." Finding the truth on this third question called for what we may call 'population studies'.

It seems to me that there were very sensible people gathered at that Exhibition, sixty-one years ago; and that the time is overdue for something of a progress report.

Looking first at the branch that was inspired by the American exhibit, we see in the past sixty years an enormous accumulation of knowledge, and an increase of certainty. Many of the thousands upon thousands of species of animals and plants in the sea have been described, named and classified. The majority of these are in the plankton, that is, the free-floating population, mainly of very small animals and plants, which are found principally in the surface and near-surface layers of the ocean, and in the shallower seas in all layers. Even those animals whose habit is to live near the bottom or near the shore, with few exceptions, begin life as members of the plankton. Besides their structure, something is also known of the behaviour of these animals and plants. Although their active motion in the horizontal is very limited, they appear to have some control over the layer at which they swim, and undertake more or less regular daily migrations—generally to the surface at night and to deeper layers by day. The surface and deeper layers of water often move differentially. Thus by the movements of horizontal layers of water, plankton organisms do effect some horizontal movement, almost like balloonists. It also seems that some of them settle on or very close to the bed of the sea at times, leaving it at others. But there is much about the behaviour of plankton that is still unknown.

It is also now known that the major seasonal changes in numbers of the plankton are closely related to the supply of nutrient salts in the water; shortage of nitrate, phosphate and silicate being liable to limit the growth and multiplication of the plant forms. Here too, though, there is much that is unexplained. Knowing also that the supply of these nutrients varies with the great water movements, which in their turn are correlated with major meteorological changes, investigators are reaching out to a statement of correlated fluctuations—in weather, fisheries, agriculture, water and plankton. This much indeed is known, that particular species are found in different water masses, and their presence denotes an incursion of that kind of water. An example is afforded by three species of the arrow-worm, each of which is confined almost entirely to one kind of water—inshore, Atlantic, or mixed coastal.

Turning to the animals that live on the bed of the sea, it is now known that these tend to occur in more or less well-marked ecological communities, depending on the nature of the ground; but that their numbers are liable to great fluctuations according to the variations in the current that carries the larvæ.

As an example of the application of this general marine natural history to fisheries, we may remember that great concentrations of some of the more spiky diatoms have been found to exclude herring from the normal fishing grounds; and that a start has been made in providing guidance to the fishermen accordingly.

Principally, though, the researches that have provided all this knowledge are to be regarded as research for its own sake, rather than as yielding this or that means for directly making a profit; and I would add that without the confidence that the main lines of nutrition, competition and mortality have been brought within human ken, I for one would not feel bold enough to make the recommendations that come from more closely applied researches. Pure research reveals the background, and the background enables the applied research worker to use judgment, which he would otherwise be quite unable to do for lack of perspective—and judgment is the most valuable weapon that can be provided in practical matters.

For a progress report on the first requirement stated at the Exhibition, general marine biology, there is ample material with which to satisfy our predecessors. This is largely to the credit of the laboratory of the Marine Biological Association and of its many relatives. I think that Huxley, Ray Lankester and Alward would all be reasonably pleased.

The second requirement was knowledge of the life-history of the food fishes—cod, haddock, plaice, hake, herring, and other less quantitatively important kinds, such as sole, turbot, whiting, mackerel and sprats. Here progress was slow at first, mainly for two reasons. First, researches were mostly confined to the waters near the shore. Observations in bays and inlets were valuable, but they could not be generalized to the much greater population of fish which the fishermen were taking in the open sea. It is true that occasional voyages were made in commercial trawlers, and these are, and always will be, necessary as part of the work of a fishery naturalist because that is the only way in which the naturalist can sample the world of fishing methods and people. Without intimate knowledge of fishermen's methods and aims, a naturalist cannot read truly the fishery statistics, which can provide him with a wealth of valuable material; and unless he sees for himself what fishermen are doing, he cannot have a true conception of whether they would in practice carry out his recommendations.

But we are now considering the natural history of the fish, and here the restriction to inshore studies, with occasional voyages as the guest of the fishermen, could never produce adequate answers. For example, it was a canon of the earlier investigators that the inshore area provided the nursery for the tiny cod of 2–3 in. length, because in the late summer these could nearly always be found in the rock pools. The truth of the matter was, however, found to be very different. Some young cod are indeed found on the mile or two strip of coastline available to the earlier investigators, but the nursery area for the North Sea, as a whole, includes the Dogger Bank to Fisher Bank area, and all the grounds to the south and east, which amounts to more than a third of the whole North Sea. This information was only obtained by several expensive voyages of a large trawler fitted for research.

There are many other examples of the necessity for large-scale operations to determine essential facts in the natural history of fishes. Nowhere has this been better shown than in the matter of growth. One of the very important discoveries since the Exhibition of 1883 was that the various hard struc-

tures in fish—bones, scales or otoliths—showed rings on them corresponding with the age of the fish. This discovery, or rediscovery, was made by Hoffbauer in 1892 for carp, and at the beginning of this century it was being applied to the sea fishes. Not all the scales give correct readings in temperate waters, but most of them do, and the record of winter on the scale is on the whole more reliable where the winters are more severe. With the aid of these structures the average age of all the fish in a sample can be determined. In addition, the growth of the fish in past years can also be found by measuring the growth on the scale.

My seniors have told me how at first they expected to find a characteristic growth-curve for each species —the cod, the herring, the hake and so on. This, however, eluded them; samples of cod from Iceland showed a different growth from those in the North Sea, and similar differences between different regions prevail in every species. Even in nearby regions there are differences: the growth-rate of plaice in the English Channel exceeds that of plaice in the North Sea. Recent work has shown that within the North Sea itself there are divisions: in summer a thermocline, or discontinuity in the water layers, becomes established over the deeper parts of the North Sea, denying the warmth of summer to the bed of the sea; and on grounds in that area the growth-rate of cod and of haddock is about half that in the shallower regions.

Furthermore, the growth-rate is not the same from year to year, but varies inversely with the density of the fish on the ground.

A very interesting experiment was carried out by G. T. Atkinson in the early years of this century. He brought back some plaice from the Barents Sea, from crowded grounds which had only recently been found by the English trawlers. Otoliths of plaice from there showed very slow growth. Those of his captive fish that survived, in his barrel of water on the deck of a trawler, he marked and let go near the Dogger Bank. When the marked fish were again caught it was found that they had enjoyed a new lease of life, and had started to grow with the fast growth characteristic of the ground where they had been liberated. Rather earlier, it had been discovered that removing plaice from the crowded nursery grounds of the Dutch coast to the better and more thinly populated feeding grounds of the Dogger Bank resulted in doubling their growth-rate.

All this variation has meant that determination of average growth-rate of fish became a statistical problem of alarming proportions, and it took many years before naturalists could fairly say what the growth-rate is in many regions, under various conditions. Certainly we have lost the old aim of determining a growth-rate characteristic of each species; but, curiously enough, generalization is possible in another way. In one region, the North Sea, under its normal heavy fishing, we can speak for all the important species together. For cod, haddock, plaice and herring, we can say that a good fish, by housewifely standards, is five years old, a notably large fish is ten years old, and a notably aged (and not very palatable) fish is twenty years old.

In most of these studies the only method by which generalization has been possible has been by use of the statistics of the markets. On our English and Scottish fishmarkets are found fish from every part of the North Sea, from the western waters as far as the Atlantic slope, from the Arctic as far as the ice. These fish are recorded by special men in the markets and the place of origin is noted. When all these returns are put together and summed, a series is provided by which the observations of naturalists in particular localities or seasons can be weighted, and so integrated. In this way it has been possible to trace out the main spawning areas and seasons, the main migrations, the main growth-rate and the main areas of immature but catchable fish. So have commercial statistics made possible the solution of problems in natural history.

I put the absence of good statistics as the second barrier to progress in the early years of the science.

It would not, however, be correct to suggest that inshore researches have contributed little or nothing to knowledge. That is far from being the case. Where those researches have led to the statement of a principle, this has been found of general application. Thus sea creatures tend to move upstream to spawn —this is true for the crabs of the east coast of Britain, for cod, plaice and many other fish in the North Sea, for salmon in rivers, and even for eels in the Atlantic Ocean.

Migration before spawning is connected with a period of helpless drift in the life of the eggs and larvæ, which is part of the life-history that has only been traced out by special voyages of investigation, and of which still too little is known. It is tolerably certain that the fluctuations in numbers of the fish population are determined during that six to ten weeks of life in the plankton, but the factors in the process have not been evaluated.

By this kind of research, repeated for many species of fish in different regions, the position has been reached that we know the outline of the natural history of nearly all the populations of fish in the northern hemisphere that provide the staple sea fisheries—and something of those in the southern hemisphere.

I think that the shades of Huxley, Ray Lankester and Alward would take a good deal of interest in this progress since 1883. The requirement stated for thorough investigation of the life-history of the food fishes has, in fact, been met. The only criticism that I can imagine them making would be that it would have taken thirty years instead of sixty if they had had a hand in it.

I should expect, however, a good deal of trouble with Huxley over the third requirement—what I have called the population problem of fish and fishing. My first statement here would be that, far from the catch being an inconsiderable proportion of the stock of fish in the sea, the industry has now grown until, for heavily fished stocks such as the plaice, cod and haddock of the North Sea, the catch in this century has become about 70 per cent of the fishable stock.

Here I should, rightly, be challenged to produce the evidence for a statement that presumes to know the number of fish in the sea; and I should say that there are two independent lines of evidence which agree in making the catch of that order of magnitude. First, naturalists of all countries have marked large numbers of plaice and cod with numbered buttons, and let them go in the sea again. The same has been done for halibut in the Pacific and for several other species in various parts of the world. Marking fish has been a most fruitful technique; and fishermen have become well used to recognizing marked fish and returning the mark, or both mark and fish, to our officers at the ports. With due precautions and

adjustments for lost marks, the percentage of fish liberated that is returned to us through the commercial fishery is an index of the percentage of the stock that the commercial fishery takes. That is the first line of evidence. The second is this. In the 'nineties, Henson and his colleagues started to sample plankton quantitatively, including the floating fish eggs. In the hands of Buchanan Wollaston, particularly, this method has been developed, until an estimate of the total number of eggs liberated in a season can be made. This number of eggs can be converted to the number of mature female fish, and that again to the number of fishable fish of that species in the sea. From the commercial statistics we can estimate the number of fish in the catch; and so we have an estimate of the ratio of catch to stock.

Both these estimates have only been possible for one population of fish, the plaice in the North Sea. However, in the commercial statistics of cod and haddock there are certain signs, namely, the fall in the catch per unit of fishing power, the increasing scarcity of older fishes in the catches, and the recovery that these stocks make when fishing is interrupted, all of which indicate about as high a rate of fishing on haddock and on cod in the North Sea as on the plaice, for which our special technique has given a numerical estimate.

So, the nature of the case, from which Huxley argued, is by now very different from what it was in the past. Already, in those days, the catches of the deep-sea fishing smacks were showing a noticeably smaller weight of flat fish caught per vessel than had ruled formerly, and the same phenomenon has continued since, in every fishery where the fisherman has power at his command, and is not limited by his market. This phenomenon, reduction in weight caught per unit of fishing power, is a very common one all over the world. It undoubtedly shows a reduction in the weight of fish in the sea, and a reduction in the return to the fisherman per unit of effort.

By way of an example let me quote what I believe to be the very earliest statistics to show this phenomenon.

CATCH PER TRAWLER PER ANNUM OF SOLES AND BUTTS

| | Tons | cwt. | To the nearest ton |
|---|---|---|---|
| 1864 | 15 | 5 | 15 |
| 1865 | 11 | 15 | 12 |
| 1866 | 9 | 4 | 9 |
| 1867 | 8 | 10 | 9 |
| 1876 | 4 | 14 | 5 |
| 1880 | 5 | 1 | 5 |
| 1881 | 4 | 19 | 5 |
| 1882 | 5 | 15 | 6 |

The story is just the same wherever a fishery has developed.

It is evident, therefore, that if a fisherman is to continue to earn a living, he can only do this by increasing his efforts. He must work harder, and invent new and better fishing gear, or use a larger or faster ship. In that way each man can continue in business. But, of course, this reduces the weight of the stock still more.

I have talked of the weight of the stock in the sea being reduced, but in all fisheries where there are good statistics this has not at first meant any reduction in the total weight landed each year. On the contrary, the fishery as a whole grows each year at first. But experience has shown that the process does not continue indefinitely: there comes a stage where an increased effort produces no increase in total weight caught; and in fact there are many fisheries where a decrease has followed.

At the stage when increasing effort produces no greater catch commercial depression sets in, and becomes chronic. I am here only describing known facts, but facts that were unknown in 1881, and not conceived possible by Huxley and by those who thought with him.

I will not here recount the mechanics of this characteristic process—a falling weight per unit of effort, and a total yield that first rises, then rises no more, and sometimes falls: but it is in fact all explicable in terms of the growth-curve of individual fish, and of the rate of mortality by fishing and the rate of mortality from natural causes. These relations have been demonstrated in papers written since 1935, or before, and are thus well established. A broader explanation is probably of more use here. I can put it this way. You can fish at a *high* rate and take a large percentage of stock kept *small* by that high rate, or fish at a *low* rate and take a small percentage of a stock allowed to grow *big* by that low rate. Or you may have your equilibrium at any point in between—or so it seems to me; because I believe that the multifarious systems of animals and plants behind the fish stock can nourish young fish or old using different food chains. The catch is therefore stock × fishing, with one going up as the other goes down. Personally, I do not find it at all surprising that extremes of values of the factors give a less product than intermediate values of both.

If, for the present purposes, it is allowed, on the grounds as it were of symmetry, that moderate fishing will give the greatest yield—and the student who has more time at his disposal may check the precise evidence for that conclusion—then some very serious and far-reaching consequences follow.

Let us look at a commercial consequence first. It is necessary to explain that the great steam-trawling industry of Britain has expanded by adventure—that is, by successive exploitation of new grounds, always farther and farther afield. In the years preceding the War, the far Arctic was the new Eldorado, where the cod was still at an early stage of the fishery, where the more you fish, the more the total catch rises. But on all the nearer grounds, such as the North Sea, Irish Sea, and Atlantic Slope, the total catch has ceased to rise long ago.

Yet the traditional psychology of pursuit remains, and whenever these near-waters fisheries appear promising, more ships, or better gear, or better fishermen, immediately engage.

Experience shows that this may be successful for a little while, as when new trawls were profitable in the North Sea for about three years from 1924 onwards; but of course the new effort drives the stock down to a new low level, and the fishery is unprofitable again.

So the net effect of the psychology of adventure is to give an average equilibrium, governed only by the equation:

$$\text{Average profit} = \text{nil}.$$

This is what happened in the Dreary Thirties—as there is ample independent evidence from account books to prove.

The Great Law of Fishing is that unlimited fisheries become unprofitable. It is clear that the

only adequate measure to conserve the fishery is to set some limit to the amount of fishing. The alternative is what we have in fact seen, the history of boys not being so unwise as to join an industry where unexampled hardship is coupled with such unattractive prospects.

However, the moment you agree to set a limit to fishing power, you find that you have in practice taken on responsibility for the way of life of the fishermen—and that brings me to the social consequence of the natural law of the stock of fish. Here it seems to me that Huxley would be on my side. He had such a practical and clear-sighted appreciation of arrangements as they affected people, as he showed in his statement of the position of the crofters, in the passage that I have quoted.

No one likes ordering the lives of other people, but control forces us either to order them or to disorder them; and to order them seems to me to involve fostering all the qualities that we admire in them. Thus we could foster individual enterprise, inventiveness, skill, technical improvement, better conditions, and any other thing that we know to be good.

Thus it seems to me, at any rate, fishery science has in these sixty years since the Exhibition brought in the power of knowledge. I do not suppose that we have more than a first approximation to the truth yet—in many departments of the science—but we have that approximation established beyond any doubt whatever, and we know exactly what has to be done.

In 1868 the scientific attitude liberated the fishery from unnecessary regulations, and allowed it to become great. But the industry has now reached the bounds set by Nature, and science, which allowed the child to grow to manhood, has now the knowledge to say what is proper in a mature industry, dependent on a natural resource.

## SYNTHETIC RUBBER PROBLEMS

THE chairman of the Division of Rubber Chemistry of the American Chemical Society, at the spring meeting of the Division in April in New York City, well said that while the achievements of rubber technologists with natural rubber in a hundred years of progress are a subject for just pride, the actual production work with synthetic rubber in less than a hundred weeks is nothing short of a miracle.

Nevertheless, the processing problems involved in using *GR–S*, which is the butadiene–styrene polymer mass-produced in the United States to replace the million tons of natural rubber in enemy hands, are still numerous, difficult, and of serious significance to the available output and service life of the products. There is ample evidence of this in the papers read before the Rubber Division, the great majority being devoted, directly or indirectly, to *GR–S* processing difficulties.

Six to twelve months ago, the rubber manufacturer's primary anxiety was to masticate, plasticize and render self-adhesive or 'tacky' the *GR–S* mixings from which rubber articles are built or moulded. No entirely satisfactory methods are yet available for this work, but provisional practical processes have been made generally known with which we can 'make do' until better are found. The relief from this anxiety has transferred attention to vulcanization difficulties, of which the variability aspect is the worst. A paper by F. E. Rupert and F. W. Gage reveals that atmospheric humidity is a factor of the first importance in the question. Exposure of unvulcanized mixings to increased humidity and increased length of exposure increases the rate of vulcanization by as much as one hundred per cent. Other evidence has been accumulating for some time, all indicating that very exact control of the water content of *GR–S* mixings is of vital practical importance.

Revolutionary ideas on the acceleration of vulcanization were given in a paper by A. A. Somerville in announcing two new copper compounds as being several times as active as conventional accelerators. So little as 0·01 per cent by weight of ordinary 300-mesh copper powder added to a *GR–S* mix will shorten the vulcanization period by half, and the new copper compounds are even more effective. Moreover, instead of the rapid perishing frequently encountered in natural rubber contaminated with copper, *GR–S* articles containing the copper accelerators actually have increased resistance to ageing. Sixteen other metals failed to show these remarkable effects.

Equally novel was a paper read by G. M. Wolf, T. E. Deger, H. I. Cramer, and C. C. de Hilster, on the successful use of a new class of vulcanizing agents —alkyl phenol sulphides, in particular *p*-tertiary-amylphenol disulphide. These agents are claimed to possess two very important advantages over sulphur in that (1) they impart some tackiness to *GR–S* mixings, and (2) they give products with outstanding resistance to deterioration by heat. The heating up of large tyres in use, which is the most serious of the unsolved production problems, since the only remedy at present is to use up the scanty stocks of natural rubber, may at least be ameliorated by the application of these sulphide vulcanizers. The heat build-up problem was touched upon, also, in a paper by G. M. Massie and A. E. Warner, who report that the use of a non-persistent accelerator, for example, a substituted lead dithiocarbamate, much reduces the tendency of *GR–S* to stiffen due to service heat, especially if diphenyl-ethylenediamine is used in the mixing.

A third paper, by A. R. Lukens, was also associated with the heat-stiffening question. It was pointed out that the trouble arises mainly from the presence in *GR–S* tyres of liberal loadings of very fine particle carbon blacks. Such loadings have become customary since the other reinforcing agents often used in natural rubber—zinc oxide, magnesium carbonate, whiting, for example—fail to confer any improvement in *GR–S*. It has now been shown, however, that mineral pigments such as those noted can be prepared in much more finely divided forms than hitherto, with the result that they considerably reinforce *GR–S*, but do not cause heat build-up. Mixings containing lower proportions of carbon black and these new fillers may well be a great improvement on to-day's practice.

Other papers at the meeting dealt with various standard problems, adding much valuable information without conspicuous novelties. Reference may be made in conclusion to an account by R. A. Emmett of an interesting range of raw materials comprising blends of various butadiene rubbers with plasticized polyvinyl chloride. Both vulcanizable and non-vulcanizable plastics have been developed in this range. They possess the good qualities of both components and provide a much-needed economy in rubber in a wide variety of applications.

# OBITUARY

## Dr. Ida Smedley-MacLean

THE death of Ida Smedley-MacLean on March 2 is a grievous loss to her many friends and has left a blank in her various fields of activity which it will be hard to fill. The British Federation of University Women, which she was largely instrumental in founding, owes much to her for her devoted service and for the breadth of vision she brought to its work. A resolution passed by the fellowship of the International Federation of University Women at a meeting in Washington on May 6 refers to one of the phases of work which she helped to launch and which has grown into a very valuable contribution to original investigation. The resolution reads as follows: "That the Fellowship Awards Committee of the International Federation of University Women records its grief at the grave loss suffered by the International Federation of University Women in the death of Ida Smedley-MacLean who for so many years played a leading part in the establishment and awarding of our International Fellowships, and who in her own work set a high standard in that type of scholarly research which we have tried to foster".

WINIFRED CULLIS.

After graduation at the University of Manchester, Dr. MacLean (then Miss Ida Smedley) worked on certain problems in pure organic chemistry under Prof. H. E. Armstrong, investigating *inter alia* the cause of colour in the dinitrobenzenes. She also acted as demonstrator in chemistry and carried out researches on problems concerning the increase in molecular refractivity of compounds containing a conjugated ethenoid linkage structure. This work resulted in a very interesting communication on the diphenylbutadienes and hexatrienes published in the *Journal of the Chemical Society* of 1908. Shortly after this early work, Miss Smedley was awarded a Beit Memorial Research Fellowship and went to work in the Biochemical Laboratories of the Lister Institute under Arthur Harden, chemist-in-chief. These laboratories had just been constituted by amalgamation of the Laboratories for Pathological Chemistry under J. B. Leathes (later of Toronto and Sheffield), with the Chemical Laboratory under Harden. One must suppose that about this time Miss Smedley developed that intense and lifelong interest in problems of fat metabolism. Study of fat metabolism and fat synthesis had already been actively pursued at the Institute by J. B. Leathes and the school he there established. It was, however, a field in which few then delved. Dr. Hugh MacLean, who later took a great interest in the study of the lipins, arrived at the Institute as one of Harden's assistants about the same time as Miss Smedley, and their marriage took place in 1913.

Dr. Smedley-MacLean perceived early the biochemical significance and importance of fats. Though to-day much is obscure in the biochemistry of fat, her work has made a valuable contribution to our knowledge of the subject, and particularly to those parts of it which deal with the oxidative breakdown of fatty acids *in vitro* and their synthesis by living organisms. Her early investigations in the field led to the deduction of the presence of a decylenic acid in butter fat, a deduction confirmed by isolation at the hands of other workers some years later. In 1912 appeared two papers in the *Biochemical Journal* on a possible mode of synthesis of fatty acid *in vivo*, in collaboration with Eva Lubrzynska. Laboratory experiments on the condensation together of such simple compounds as aldehydes and pyruvic acid led to the isolation of longer carbon chain substances of a fatty nature. The work crystallized itself in the hypothesis that pyruvic acid was a very probable starting point for the synthesis of fatty acid in the body. It is a hypothesis which merits to this day the most serious consideration by students of the subject. Even now we do not know the actual steps by which fatty acids are built up from carbohydrates *in vivo*. Of added interest and significance in this connexion are the later investigations of other workers on the importance of pyruvic acid in carbohydrate transformations.

With the War of 1914–18, Dr. Smedley-MacLean's energies were diverted to other pressing problems. With Dr. Chaim Weitzmann she worked on the problem of producing acetone on the large scale from starch by fermentation, a project which was eminently successful. With the end of the War, and in spite of greatly increased domestic responsibilities, Dr. Smedley-MacLean again threw herself with great energy into the well-loved work, and many important and interesting papers on the mode of synthesis of fat and carbohydrate in yeast appeared at intervals until about 1939. While seeking a possible laboratory model for the study of the biochemical oxidation of fatty acids, she discovered that hydrogen peroxide in the presence of a cupric salt as catalyst is extraordinarily powerful in its oxidizing action on fatty acids. Within a short time the higher fatty acids may be largely broken down to carbon dioxide, a chemical transformation very difficult or impossible to perform in any other way. This field she cultivated with success up to some few weeks before her death.

From about 1935 onwards interest centred on the fat-deficiency disease of rats discovered by Burr and Burr in 1929 (*J. Biol. Chem.*, 82, 345; 1929). At the Lister Institute the physiological aspects were more closely studied in conjunction with Miss Hume and Miss Henderson-Smith, while the biochemical side was left to Dr. Smedley-MacLean and myself. Her delight and fascination with this work never left her. Besides many other interesting and significant points uncovered, the position of linoleic acid as the probable precursor of arachidonic acid and other very highly unsaturated acids was established. The nature of the fatty acids stored under conditions of disease and cure was also investigated. Finally, the structure of arachidonic acid itself (originally discovered by P. Hartley in 1909 in the same laboratories) was put forward as a result of investigation on a very small quantity of material. The suggested structure was fully confirmed by subsequent work with larger quantities in the United States.

Much has been omitted from this brief note, but it is hoped that sufficient has been said to indicate the late Dr. Smedley-MacLean's comprehensive and intense interest in the biochemistry of fat. I worked with her for many years, and I retain the sense and knowledge of her masterly grip of her field. She sought out the facts, made very sure of them and then held to them amid much cross-fire. She saw the significant correlations between her facts very clearly and rarely went beyond. As a teacher and colleague she never failed to inspire, and there must be many like myself who look back on their "Lister" days with intensely happy memories.

LESLIE C. A. NUNN.

# NEWS and VIEWS

## Engineering Science at Oxford: Dr. Alexander Thom

DR. ALEXANDER THOM, who has been appointed to the chair of engineering science in the University of Oxford, graduated in engineering in the University of Glasgow in 1915, and after a varied experience in civil engineering construction both abroad and in Great Britain was engaged in aircraft design in the later years of the War of 1914–18. In 1921 he was appointed lecturer in engineering in the University of Glasgow, and from that time until the beginning of the present War, Dr. Thom was in charge of the subject of aeronautics and also of the specialist courses in civil engineering. This somewhat unusual combination was of considerable value to the teaching in both subjects, and large numbers of engineering students in all branches have benefited in their scientific training from the lectures in aeronautics given by Dr. Thom. His tenure of the post was marked by a large volume of research work in aerodynamics, comprising exhaustive studies of the flow of a fluid past a cylinder, stationary and rotating, employing both a small wind tunnel and, for an experimental investigation of the pattern round a cylinder at low Reynolds numbers, a small channel using water and oil. In the course of his studies he developed an arithmetical method of solution of the equations of flow for both ideal and viscous fluids. The results of his researches, which have throughout been characteristic of the originality of his mind, have been embodied in numerous papers contributed to Reports and Memoranda of the Aeronautical Research Committee, the Royal Society and the scientific and technical Press. Shortly before the outbreak of the present War, he was given leave of absence from his university duties to engage in work at the Royal Aircraft Establishment, Farnborough, and has latterly been in charge of new developments in the Aerodynamics Department.

## Twenty-fifth Anniversary of the Genetical Society

AT its annual meeting on July 21 the Genetical Society completed the twenty-fifth year of its activity. A gathering was called on June 25, 1919, under the chairmanship of William Bateson, at which it was agreed to found the Society, and the first meeting was held on July 12 of that year. The original list comprised eighty-seven members, and the first president was Mr. A. J. (later Lord) Balfour, who held office until 1930. The Society's eighty-two meetings have been mainly devoted to communications on fundamental genetics, including also addresses by such foreign visitors as Drs. T. H. Morgan, H. J. Muller, A. H. Sturtevant, C. B. Bridges, R. Goldschmidt and Ø. Winge. Interest has, however, not been confined to this narrower field, but, as Bateson intended, has also covered plant and animal breeding, human and medical genetics and, of course, cytology and evolutionary theory. Visits have been made on a number of occasions to plant and animal breeding centres and exhibitions, as well as to Kew Gardens, East Malling and Rothamsted Research Stations, the Lister Institute and the Gardens of the Zoological Society. Joint meetings have been held with the Society for Experimental Biology and the Entomological Society, and doubtless this kind of activity will increase in the future as the applications of genetics become more widely appreciated. The Society also sponsored the Seventh International Congress of Genetics held at Edinburgh in 1939.

Before the War, three or four meetings were held annually. This programme was interrupted in the early years of the War; but since 1941 a return has been made to the pre-war arrangement. The present aim is to hold one symposium and one paper-reading meeting during the winter and spring months, and to visit some appropriate research centre in the summer. The present membership numbers 146, of whom twelve are overseas. Dr. C. D. Darlington is now president and Dr. E. B. Ford and Mr. W. J. C. Lawrence are joint secretaries.

## Education of the Pharmacist

AT the British Pharmaceutical Conference held in London on July 11, the chairman, Mr. H. Brindle, gave an address on the "Education of the Pharmacist". He reviewed the present system of pharmaceutical education and commented on the possible effects upon it of the Norwood Report and the Education Bill. The present qualifications in pharmacy include two diplomas granted by the Pharmaceutical Society: that of the chemist and druggist, and that of the pharmaceutical chemist. In addition, several universities have established degrees in pharmacy. All the diplomas and degrees are registerable qualifications for practice. The chemist and druggist diploma is mainly utilized as the qualification for retail practice, but Mr. Brindle hopes that the higher diploma and the degrees will be in greater demand. Retail pharmacy needs its share of the best brains and the most highly trained pharmacists. It offers opportunities certainly comparable in all respects with those of the other branches of the profession, such as hospital, manufacturing and research.

The Pharmaceutical Society in the past has demanded the university entrance standard for its preliminary examination and Mr. Brindle hopes that this will be maintained. The Norwood Report, however, foreshadows certain complications for retail pharmacy because of the recommendation that the general age for entering a university will in future be eighteen plus. This must lead to an alteration in the present system of apprenticeship. He suggested that apprenticeship has largely outlived its usefulness, and if it is to be retained it might with advantage occur after qualification. The university degrees in pharmacy are now well established, and the graduates are proving their value in ever-widening scientific fields. Mr. Brindle hopes that the post-war educational world will provide facilities for brilliant students unhampered by financial handicaps and that university education will be free to all who show themselves capable of benefiting by it.

## Veterinary Practice by Unregistered Persons

IN accordance with the recommendation made by the Loveday Committee on Veterinary Education in Great Britain, the Minister of Agriculture and Fisheries and the Secretary of State for Scotland have appointed a Committee to inquire into the extent and effect of veterinary practice in Great Britain by persons who are not registered veterinary surgeons, and to make recommendations as to any measures which may be desirable to limit or regulate such practice. The Committee is constituted as follows: Sir John Chancellor (*chairman*); Mr. A. C. Brown; Sir Daniel Cabot, chief veterinary officer, Ministry

of Agriculture and Fisheries; Mr. J. W. Salter Chalker, chairman of the Diseases of Animals Committee of the National Farmers' Union; Mr. Charles Dukes, general secretary of the National Union of General and Municipal Workers; Prof. James Gray, professor of zoology in the University of Cambridge and member of the Agricultural Research Council; Mr. C. M. Holmes, vice-president of the Association of Unqualified Practitioners and Animal Castrators; Mr. W. F. Holmes, member of Council of the Kennel Club; Mr. Robert Hobbs, member of Council of the Royal Agricultural Society of England; Mr. W. D. Jackson, past president of the National Farmers' Union and Chamber of Agriculture of Scotland; Sir Louis Kershaw, member of the Loveday Committee on Veterinary Education; Lieut.-Colonel P. J. Simpson, member of Council of the Royal College of Veterinary Surgeons. The Secretary to the Committee is Mr. G. H. Higgs, of the Ministry of Agriculture and Fisheries, to whom communications should be addressed at 99 Gresham Street (First Floor), London, E.C.2.

### Biological Standardization

BIOLOGICAL standardization is the theme of the *Bulletin of the Health Organisation* (VI, **10**, No. 2; 1942–43. Geneva (London: Allen and Unwin, League of Nations Publications Dept. 4*s*.)). The issue contains two articles on the biological standardization of heparin and on a provisional international standard for this substance, and other articles on standard preparations for the assay of the three gas-gangrene antitoxins, on the complexity of the tetanus toxin and on the variable interactions of tetanus toxins and antitoxins. The rest of the issue is occupied by seven articles from the Department of Biological Standards of the National Institute for Medical Research, London. The first of these deals with recent changes relating to international standards for certain sex hormones and for pituitary posterior lobe, due to exhaustion of stocks of the original preparations which had served as international standards for these hormones and the consequent need for their replacement by other samples. The other six articles deal with replacements of the substances of the international standards for the œstrus-producing hormone, for male hormones, progesterone and pituitary posterior lobe and with the international preparation of desiccated ox anterior pituitary gland and the international standard of prolactin.

### Status of Statisticians

THE report of the Committee of the Royal Statistical Society on the Status of Statisticians, appointed by the Council on July 22, 1943 as amended and adopted by the Council, has now been issued. The present position in Great Britain is regarded as unsatisfactory in some respects. First, an employer requiring the services of a statistician on his staff has no common standard among the qualifications which he can accept as a certificate of proficiency, and the report, in confirmation of this point, notes that in recent discussions on the Society's report on official statistics, the Treasury representatives indicated how useful it would be to departments, in considering appointments to responsible positions in statistical branches, if approved statistical qualifications were in existence. The position is also unsatisfactory to an employer, because there are no generally recognized definitions or descriptions of the various types of statistician. It is equally unsatisfactory to the employee, because there is no recognized status in his profession and no generally approved method of distinguishing between a genuinely accomplished man and a mere quack, or even a rank impostor. It is also unsatisfactory to an employee not to have any standards by which he can judge the level of his own attainment, or to which he can work. The situation is unsatisfactory for the general public, which is affected more than it realizes by bad statistical work.

The Committee considers, therefore, that there is a strong case for instituting some method of determining the professional status of statisticians. It believes that the universities must continue to be the main source of training in statistics, and it would welcome any extension of the facilities already provided, although it does not think that the universities can provide adequate tests of proficiency in statistics for all who are likely to require them; also, existing examinations are not sufficient to provide all the requisite professional qualifications. Accordingly the Committee proposes a scheme under which power would be sought by way of a Supplemental Charter to enable the Council of the Royal Statistical Society to confer on approved candidates a diploma in statistics and to issue a certificate to those who pass Part 1 of the examinations. This would provide specifically for those who may be termed statistical computers or junior statisticians. Candidates for the certificate or diploma should not be limited to fellows of the Society, and those for the diploma should be required to pass Parts 1 and 2 of the prescribed examinations, a suggested syllabus for which is appended to the report, and also to show that they had had satisfactory experience of statistical work over a period of not less than two years. A candidate for the certificate or diploma should be exempted from the whole or any section or sections of the examinations if he has passed examinations approved by the Council. While so far as concerns the scientific aspects of the Society's work, no change is suggested in the present system of election of fellows, in the qualifications required, or in their title, status and privileges, additional by-laws would be required to regulate the award of the certificate and the diploma.

### Astronomy in the U.S.S.R.

POST-WAR astronomical research in the Soviet Union is being planned on a great scale. Nine of the nineteen Soviet observatories were in territory that was overrun by the Germans and have been destroyed or seriously damaged. Most important of these was the Pulkovo Observatory, near Leningrad, which was completely destroyed by air and artillery bombardment. Most of the equipment and the valuable library of the Observatory were removed in time to safer places. The Pulkovo staff has continued astronomical research work at Tashkent, Abastumani and Alma-Ata. Prof. Belyavsky, director of the Observatory, states that it has been decided that reconstruction is to commence immediately and that the instrumental equipment will be reinstalled at Pulkovo at the earliest possible moment, to make possible the resumption of work in fundamental astronomy. More powerful equipment is to be constructed in the U.S.S.R. or obtained from abroad. The Engelhardt, Nikolaeff and Tashkent Observatories will also carry on fundamental observations.

The *Moscow News* has reported the decisions of

an astronomical conference held in Moscow in September last. A great astrophysical observatory is to be established with headquarters at Simferopol in the Crimea. There will be three observing stations, one in the Crimea at an altitude of 2,000 metres, a solar station at an altitude of 3,500 metres, and a station somewhere in the southern hemisphere. The equipment will include a 120-in. reflector, two 80-in. reflectors, two 16-in. double astrographs, one 50-in. and one 30-in. Schmidt telescope, solar towers and a coronagraph. The training of astronomical staff has continued during the War; some sixty or seventy astronomers and astrophysicists will be required for staffing the new institution. Information has been received that the international latitude station maintained by the U.S.S.R. at Kitab, Uzbekistan, has continued to function regularly throughout the War.

### Library Service in South Africa

IN his presidential address to Section F of the South African Association for the Advancement of Science delivered on June 29, 1943, on "Libraries and Science" (*South African J. Sci.*, 40, 81; November 1943), P. Freer referred particularly to the difficulties of book selection in scientific literature. He urged that this is not a matter for librarians alone, and that librarians should also do more to secure the writing and publishing of authoritative but simple and readable books on important subjects. After pleading for more care and co-operation in the discarding of surplus or unwanted stock, Mr. Freer indicates measures that are required for the full efficiency of the inter-library loan system. Until the master-catalogue of non-fiction in the libraries of the Union of South Africa is completed, as well as the publication of a new edition of the Lloyd's List of Scientific and Technical Periodicals, with a complementary volume covering the humanities, book-buying and discarding are both unscientific. As regards the imperfections and limitations of present abstracting and indexing services for scientific and technical periodicals, Mr. Freer notes that only forty-one of the three hundred abstracting and indexing periodicals in existence in 1937 were available somewhere in South Africa, and these periodicals only covered one third of the scientific papers concerned. He emphasized the need, for the advancement of science, of a highly trained staff and augmented resources to diminish the gap between the 6,000 titles in the Catalogue of Union Periodicals and the 15,000 acknowledged as being of international importance. Plans for post-war reconstruction contained no suggestions for a national library system, but in addition to national libraries, regional libraries and organization would be required. Finally, he referred to the contribution which science could make to the improvement of the printed book itself and its preservation.

### Mexican Institute of Nutrition

ACCORDING to an annotation in the September issue of the *Boletín de la Oficina Sanitaria Panamericana*, the newly organized Institute of Nutrition in Mexico includes the following sections: bromatology, economic, social and dietetic departments, clinical medicine and a clinical laboratory, and maternal and child welfare. In the near future, the bromatology section will undertake studies of the chemical composition of legumes and maize, and the economic section will undertake an investigation of the state of nutrition of about seven hundred families in an area of Mexico City. The clinical laboratory will determine the vitamin content and blood count of the families studied. The maternal and child welfare division has already started work on the vitamin content of the blood of pregnant women at different periods of pregnancy, and a training centre has made plans for courses for the selection of dietitians and experts in nutrition.

### An Automatic Vibration Analyser

ONE of the potential causes of failures in an aeroplane power-plant or the aeroplane structure itself is excessive vibration. While every effort is made to reduce the number of modes of vibration which might be excited to objectionable amplitudes, it is desirable to measure the power-plant and aeroplane vibration characteristics in flight to ensure that there are no vibrations of sufficient magnitude to cause fatigue failures in any parts. In the Bell Laboratories an automatically tuned wave analyser has been developed to meet the needs of the Pratt and Whitney Aircraft Division of United Aircraft Corporation, which desired apparatus that when used in conjunction with suitable vibration pickups would measure the amplitude of vibration at a frequency equal to any predetermined multiple of engine revolution per minute, even when the engine speed is continuously changed. This analyser can be used with a recorder to draw curves of the amplitude of vibration of selected orders of frequency as a function of engine speed. An article by F. G. Marble (*Bell Lab. Rec.*, 22, No. 8; April 1944) describes the analyser and its use.

### Illuminating Engineering Society

DURING the past few years the membership of the Illuminating Engineering Society has approximately doubled, it has formed new centres and groups throughout Great Britain, and its activities have greatly increased. In addition, it has in prospect a programme of still greater activity and of new developments in the post-war period. In order to cope with these developments the Council is now contemplating the appointment of a full-time paid secretary who, it is hoped, will eventually take full charge of its administration. In the meantime, however, the Council hopes to continue to benefit for some time to come from the services of its honorary secretary, Mr. J. S. Dow, who has been associated with the Society since its inception in 1909.

### Institution of Electrical Engineers: Radio Section

ON the recommendation of the Wireless Section Committee the Council of the Institution of Electrical Engineers has decided to change the name of the Section to "Radio Section" and to modify Rule No. 1, which deals with the scope of the Section, to read as follows: "The Section shall include within its scope all matters relating to the study, design, manufacture or operation of apparatus for communication by wave radiation, for high-frequency and electronic engineering, or for the electrical recording or electrical reproduction of sound".

---

ERRATA.—In the communication "Physico-Chemical Properties of the Surface of Growing Plant Cells" by Prof. H. Lundegårdh and G. Stenlid in *Nature* of May 20, p. 618, Fig. 1 and Fig. 2 should be interchanged. The absorption maximum of the flavonone is in two places in the text erroneously assigned to 2550 A. instead of 2850 A.

## A Notation for Organic Compounds

DR. A. R. RICHARDS[1] proposes a form of 'chemical shorthand' to designate the commoner hydrocarbons and their simple compounds. This he claims may avoid the practice of coining names such as 'triptane' for '2,3,3-trimethylbutane'; in practice it will not have this effect. Once a substance leaves the laboratory and enters the plant, it *must* have a short distinctive title by which all and sundry can refer to it; and in 'triptane' such a word has been found. What we must most sedulously avoid is the unwarrantable intrusion of such coined names into systematic nomenclature. G. C. Foster, so far back as 1865[2], pointed out that all sciences have two distinct requirements of nomenclature—a convenient *general* language and a systematic or 'legal' language. The former serves for the ordinary everyday transactions of science and manufacture and will, "in the main, take care of itself; and at any given period it usually contains a large admixture of terms—once technical, but now no longer used for purposes of accuracy—which, like fossils in a rock, tell of the successive changes by which the existing state of things has been brought about". The strictly legal or premeditated language of organic chemistry is for cataloguing and identifying substances with absolute precision and expedition.

At present we have a choice in the exact delineation of an organic structure between an ideograph (the structural formula) and a so-called 'systematic' name. The ideograph is space-consuming, has no sound equivalent and cannot be indexed in list form, since a series of structural formulæ has no intrinsic basis of ordered arrangement; on the other hand, it is immediately intelligible to the eye and easily remembered. 'Systematic' names are cumbrous, often ambiguous, very long to print, and have never attained more than a measure of popularity with practical chemists. They impose an intolerable burden on the memory, being related to a large group of 'trivially' named nuclei, many of which are virtually unknown. Further, they are often unpronounceable owing to the use of various types of brackets, subscripts, dashes and the like which not only complicate printing but also have no simple vocal equivalent [for example, pronounce the following: Spiro [3-naphtho [1,2] triazole-2,2′-3′-ox-2′azatricyclo [3.3.3]. nona-1′(8′),5′(9′)6′-triene] and then jot down its structure (Ring Index No. 3179)].

Most chemists actually remember the structure or ideograph and associate the idea of a name; after a time many structures and names become so closely associated as to be almost indissoluble in the memory; but such are only a small fraction of those ordinarily used, while the rules and exceptions of systematic nomenclature are tedious both to learn and to apply.

Ordinary systematic nomenclature has failed to give that degree of precision and ease of reference required by modern developments of the science, and I have developed during the past few years a system of ciphering for organic compounds which provides a method of reference and classification capable of providing a unique cipher for every structure. Such ciphers have a logical system of enumeration, use only the capital letters, θ, and the Arabic numerals, without subscripts, brackets or dashes and are, moreover, capable of being 'interpreted' on a punched card system; the 'sorting' of cards into categories can be readily accomplished and a form of mechanical indexing and reference is thus achieved. In addition, the machine can automatically compute, from the card, the empirical formula of the compound.

Space does not permit the discussion of details of this system, which will be published elsewhere shortly, but my purpose in writing will be served if attention is directed to (*a*) the inevitability of short or trivial names for substances in common use; (*b*) the undesirability of allowing such names further to complicate our systematic nomenclature; (*c*) the desirability of any universally adopted cipher system being complete, international and mathematically adaptable.

## A Silicified Member of the Cyclanthaceæ from the Tertiary of the Deccan

NEW discoveries of fossil plants, while frequently solving problems of geographical distribution, often throw up fresh problems that baffle solution. Recent work on the silicified flora of the Deccan Intertrappean Series (which with all deference to the 'official' view of the Geological Survey of India we regard as Early Tertiary and not Late Cretaceous[1]) has brought to light genera which are either identical or very closely related to living types now confined to parts of South America. A year ago, one of us reported the occurrence in these beds of well-preserved silicified sporocarps essentially of the Regnellidium type, which he referred to a new genus, Rodeites[2], closely allied to the Brazilian water-fern *R. diphyllum*. We now record the occurrence in the same locality (Mohgaon Kalan, in the Central Provinces) of a new silicified member of the Cyclanthaceæ, a family now living only in tropical America. Of this family we had hitherto no definite fossil record. The leaf-impressions from the Eocene of Sézanne, which Saporta[3] referred to a new genus, Ludoviopsis, may equally probably belong to palms.

We recently suggested[4] that the silicified stem from the Deccan, described by K. P. Rode in 1933 under the name *Palmoxylon Sahnii*[5], is probably not a true palm but an extinct member of the Cyclanthaceæ. A detailed anatomical examination of the vegetative organs of this plant, of which two large specimens were found by one of us at the same locality in 1941, has now proved that our surmise was correct. In its main anatomical features the fossil shows a close resemblance to Cyclanthus. Thus the root structure is very similar to that of the modern genus; in both forms the pith is fibrous and there are ten or more protoxylem groups. The fibrovascular bundles of the stem, which Rode described in some detail, also resemble those of Cyclanthus in the crescentic arrangement of the xylem vessels and in the peculiar compound (? branched) nature of the bundles. As in Cyclanthus, too, the leaf sheaths contain a row of large secretory canals.

The flowers and fruit of the fossil are unknown, hence the exact affinities are still rather obscure. But the anatomical resemblances with Cyclanthus are set off by the arboreous habit of the plant which, as stated last year, "must have grown rooted in shallow water, with the stems rising in a clump, somewhat like those of a bamboo"[4]. These differences, coupled with the distance in time and space which separates the living and the extinct forms, suggests that the fossil should at least provisionally be referred to a new genus of the sub-family Cyclantheæ.

The generic name Cyclanthodendron is proposed. This new genus provides (like Rodeites) another interesting link between the Early Tertiary flora of the Deccan and the modern flora of South America.

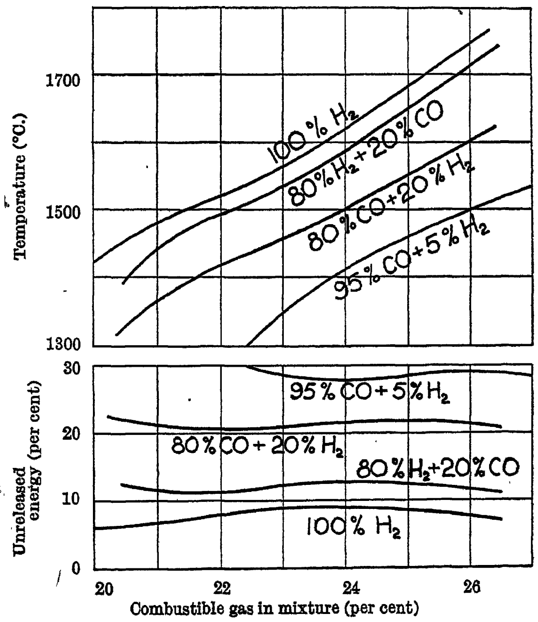
## Unreleased Energy in Flame Gases

WE recently reported[1] the results of temperature measurements made by means of very fine quartz-coated platinum wires in the flame gases resulting from the combustion of hydrocarbon-air mixtures in a specially constructed burner. From these measurements estimates were made of the proportion of the heat of combustion which was unreleased in the flame gases for the purpose of increasing their temperature. The unreleased energy, we believe, is due partly to latent energy held in stable form in some of the newly formed tri-atomic molecules and partly to abnormal dissociation resulting therefrom. It varied from about 10 per cent to rather more than 20 per cent of the heat of combustion.



Similar measurements have since been made using mixtures of air with hydrogen and with carbon monoxide plus hydrogen in various proportions. The curves in the top portion of the accompanying graph show these measurements. It will be seen that for any given mixture strength the hydrogen flame gas temperature is more than 200° C. higher than the carbon monoxide (with 5 per cent hydrogen) flame gas temperature—and this in spite of the fact that the calculated hydrogen flame gas temperatures are more than 100° C. lower than the calculated carbon monoxide flame gas temperatures. The measured temperatures have not been corrected for radiation loss, but even after making full allowance for this, the hydrogen temperatures are of the order of 150° C. below and the carbon monoxide (with 5 per cent hydrogen) temperatures of the order of 500° C. below the corresponding calculated temperatures.

Curves giving estimates of the unreleased energy are shown in the lower portion of the graph. In the hydrogen flame gases this is of the order of 8 per cent of the heat of combustion and in the carbon monoxide (with 5 per cent hydrogen) flame gases it is nearly 30 per cent. There is little doubt that in flame gases resulting from the combustion of carbon monoxide with a much smaller proportion of hydrogen it would be considerably greater than 30 per cent.

## Rayleigh Quenching of Active Nitrogen

ARISING out of work[1] on the disappearance of the nitrogen afterglow by heating the activated gas at various pressures, it may be of interest to record results which indicate limits for the production of a like phenomenon observed by Lord Rayleigh[2], namely, the quenching of the afterglow due to cooling by liquid air. With a condensed discharge in a Crookes' tube connected in series with a long glass spiral $S$, and a small bulb containing powdered iodine, the activated gas excited the characteristic iodine luminescence even when the afterglow in the observation spiral $S$ was feeble; both disappeared when $S$ was cooled by liquid air, in agreement with Rayleigh's observation[2]. That this phenomenon is, however, restricted to low pressures is shown by the fact that when the gas pressure was increased progressively from 0·1 mm. the Rayleigh quenching in $S$ tended to be less marked; was uncertain near 30 mm. and not observed above 40 mm.

A possibly insufficient cooling of the activated gas at high pressures was minimized as follows. The nitrogen was first streamed through a long spiral of glass, which enclosed the Crookes' tube; while both these were well immersed in a bath of liquid air, the gas was subjected to the discharge. A distinct afterglow was produced in $S$ even when it was cooled by liquid air, and was accompanied by luminescence in the iodine bulb. Both these effects were observed also at smaller pressures, at which under normal conditions (that is, when not cooled by liquid air before and during activation by the discharge) the Rayleigh quenching occurred. Addition of one more spiral cooled by liquid air, just before the one

surrounding the discharge tube, making the total cooling path about three yards in length, had little effect on the results. A high gas pressure and low temperature activation, therefore, are unfavourable to the occurrence of the Rayleigh quenching.

## Constitution of some Binary Oxide Systems

THE constitution of the oxide systems FeO–MnO, FeO–MgO, CaO–MnO and MgO–MnO have been studied by the X-ray diffraction method. Preparation of the powder samples was carried out *in vacuo* at temperatures up to 1350° C., followed by slow cooling to 1150° C., from which temperature the samples were rapidly cooled.

The X-ray patterns showed that the four systems are single phase. It was possible to make accurate lattice dimension measurements for all samples. The result on the FeO–MnO system is in agreement with that of Andrew, Maddocks and Howat[1] and of McCaughey[2], but in contradiction to that of Benedicks and Löfquist[3] and Hay, Howat and White[4]. The FeO–MgO system has been reported to be a single phase system by Bowen and Schairer[5], following the use of thermal and optical methods. References have not been found to any previous work on the CaO–MnO and MgO–MnO systems.

Full details of the work will be published later.

## A Molecule-building Principle

IT has long been realized in the field of molecular spectra that there is need of some form of molecule-building principle equivalent to the *Atombau* principle of Bohr. This would enable the electron configuration and term type of at least the ground-state of any molecule to be predicted from its position in the Periodic Table. Mulliken[1] attempted to trace the change in electron configuration from molecule to molecule for the lighter members of the Table, but his pioneering work was hampered by the absence of many necessary spectrum data, and no progress has since been made. In particular, very little knowledge has been obtained on the configuration of the heavier diatomic molecules.

I have been studying for some time the spectra of the heavy fluorides of the series, AuF, HgF, TlF, PbF and BiF, and it is now possible to describe their ground-states in terms of electron configurations. These are shown in Table 1, along with the corresponding iso-electronic oxides and their probable configurations.

TABLE 1.

| Molecule | AuF | HgF | TlF | PbF | BiF |
|---|---|---|---|---|---|
| Type | $^1\Sigma$ | $^2\Sigma$ | $^1\Sigma$ | $^2\Pi$ | $^3\Sigma$ |
| Config. | $\pi^4$ | $\pi^4\sigma$ | $\pi^4\sigma^2$ | $\pi^4\sigma^2\pi$ | $\pi^4\sigma^2\pi^2$ |
| Molecule | AuO | HgO | TlO | PbO | BiO |
| Type | $^2\Pi_i$(?) | $^1\Sigma$ | $^2\Sigma$ | $^1\Sigma$ | $^2\Pi$ |
| Config. | $\pi^3$ | $\pi^4$ | $\pi^4\sigma$ | $\pi^4\sigma^2$ | $\pi^4\sigma^2\pi$ |

Iso-electronic molecules connected by dotted line.

It is evident that a building principle is operating in which the configuration of a given molecule retains the structure of the preceding with the addition of an electron to the lowest available orbital.

It is of interest to note the probable configuration and term type of the molecules AuO (AgO and CuO) and BiO, the spectra of which are still in a state of confusion. More information can be derived for the $^2\Pi$ BiO state by examining the doublet separations of the $^2\Pi$ states arising from $\pi^4\sigma^2\pi$, given in Table 2.

TABLE 2.

| CF | NO | SiF | PO | GeF | AsO | SnF | SbO | PbF | BiO |
|---|---|---|---|---|---|---|---|---|---|
| (60) | 121 | 161 | 221 | (920) | 1027 | 2317 | 2272 | 8260 | |

Bracketed values are predicted in forthcoming publication.

This suggests that an electronic interval of the order of 8,000 cm.$^{-1}$ should be sought for among the many bands of this molecule.

A fuller report of this work will be published elsewhere.

## *Torulopsis utilis* and the Citric Acid Cycle

THE ordinary strain of *Torulopsis utilis* (Henneberg) deriving from Haehn[1] can easily grow on a great many substrates under aerobic conditions (cf. Fink[2]). Nevertheless, there are still many substrates to which the Torulopsis yeast can be accustomed. Among others, I have studied some of the acids belonging to the so-called citric acid cycle of Krebs[3].

In my experiments the standard Torulopsis yeast was cultivated on ethyl alcohol, ammonia and salts, including the sulphates and phosphates of potassium, magnesium and calcium. These salts being of technical quality, it is probable that they contained other elements necessary for the growth of the yeast, for example, iron.

Cultivations were carried out under vigorous aeration. The substrate, except in the earliest stages of adaptation to a new substrate, was added in small portions, using a time schedule, so that the concentration of substrate might be as small as possible.

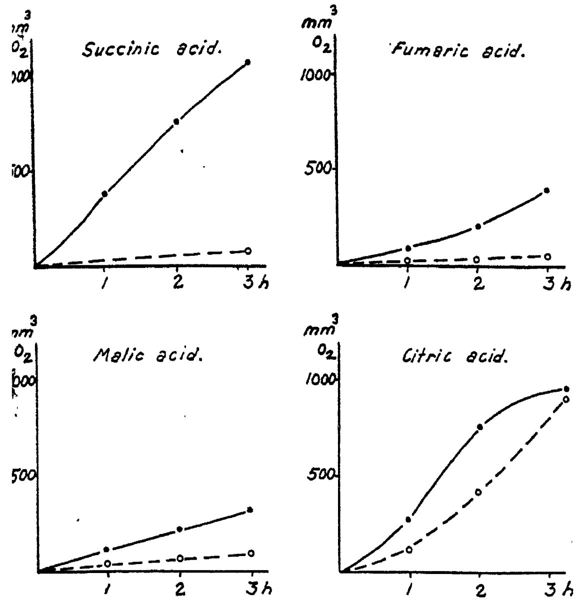

Fig. 1. UPTAKE OF OXYGEN BY *Torulopsis utilis* IN THE PRESENCE OF VARIOUS ACIDS. THE YEAST WAS ADAPTED TO SUCCINIC ACID. EACH WARBURG CUP CONTAINED 20 MGM. OF FRESH YEAST, 1 ML. 0·2 $M$ $KH_2PO_4$, 0·3 ML. 0·1 $M$ ACID, NEUTRALIZED TO $p$H 4·5 AND WATER TO 2·4 ML. THE EXPERIMENTS REPRESENTED BY THE BROKEN LINES CONTAINED ALSO 0·2 ML. 0·1 $M$ MALONIC ACID.

It was found that the standard yeast grown on ethyl alcohol could not initially use succinic acid but that it could be adapted rather easily to that substrate in the presence of ammonia and salts. It was much more difficult to adapt the yeast to malic, fumaric or citric acid, which also were not attacked initially. The yeast cultivated on succinic acid did not at first show any noteworthy new properties as detectable by adding the acids just mentioned to a suspension of yeast and determining the oxygen uptake in the Warburg apparatus. By cultivating the yeast twice more on succinic acid using the same technique, it was found, however, that the yeast had changed. It was now able to attack all four of the acids just mentioned, but not maleic, *trans*-aconitic or malonic acid. Moreover, on adding malonic acid and one of the acids succinic, malic, fumaric or citric simultaneously, it was found that the oxygen uptake was to a great extent inhibited, which had not formerly been the case (Fig. 1).

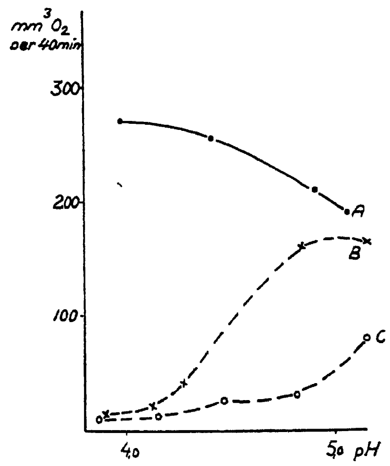

Fig. 2. UPTAKE OF OXYGEN DURING THE FIRST 40 MIN. OF THE EXPERIMENT BY THE SAME YEAST AS FIG. 1. EACH CUP CONTAINED YEAST, $KH_2PO_4$ AND WATER AS BEFORE AND 0·3 ML. 0·1 $M$ SUCCINIC ACID. $B$ ALSO CONTAINED 0·1 ML. AND $C$ 0·2 ML. 0·1 $M$ MALONIC ACID.

To ensure that the *Torulopsis utilis* had not been contaminated with any other kind of yeast, samples were spread on agar plates and found to be identical with the original yeast and very pure.

The activity of the Torulopsis yeast towards succinic acid (and towards the other acids) is very dependent on the $p$H of the suspension, being greater at acid $p$H (Fig. 2).

The property of the yeast of being able to attack succinic acid, etc., had not altered its behaviour towards other substrates such as pyruvic, lactic or acetic acid or ethyl alcohol or glucose, nor did malonic acid inhibit the breakdown of any of them. The inhibition brought about by malonic acid in the case of citric acid is merely a period of induction which lasts about one hour.

The observations described above suggest that although the enzymes of the citric acid cycle are possibly not normal constituents of the Torulopsis yeast, they can be synthesized under the conditions given. It seems justifiable to suppose that a particular enzyme effecting the breakdown of succinic acid is built up during adaptation. The action of this enzyme can be inhibited by malonic acid. The citric acid cycle does not seem to play any considerable part in the breakdown of pyruvic acid in this yeast.

Experiments have also been made to cultivate the yeast, adapted to succinic acid, on citric acid. The yeast grew well though not so fast as on, for example, ethyl alcohol or glucose. All the carbon of the substrate could be accounted for as yeast substance and carbon dioxide, indicating that no intermediates had been accumulated.

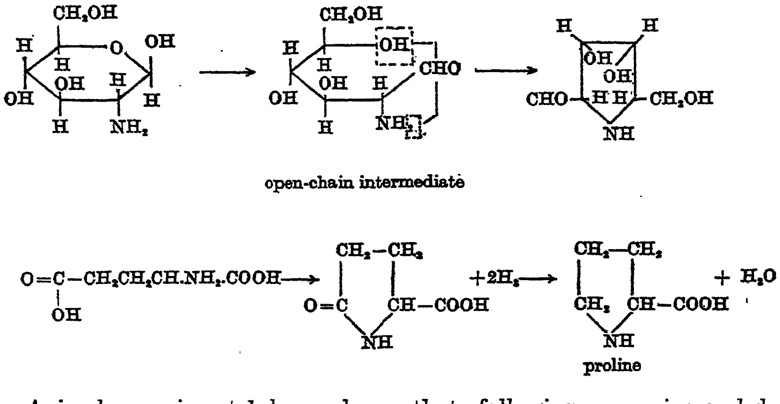
## Porphyrin Metabolism in Idiopathic Porphyria

IDIOPATHIC porphyria is especially interesting as the urinary pigment uroporphyrin III associated with this disease resembles closely in its chemical structure the protoporphyrin of hæmoglobin. Urinary uroporphyrin may provide here an index of the rate of protoporphyrin formation in the body, and it seemed important to obtain information on this point, and to observe if uroporphyrin III excretion is augmented by administration of substances which, on a theoretical basis at least, could function as protoporphyrin precursors.

With the excellent co-operation of a porphyric of mild, chronic type, investigations were made on the effect of administration of *d*-glucosamine on porphyrin excretion. It was considered that 2-amino-sugars such as 2-amino glucose or 2-amino arabinose might condense *in vivo* to form pyrrole and porphyrin derivatives which would be excreted. 2-amino glucose may be represented as a possible source of a simple pyrrolidine derivative, following a reaction

similar to the internal condensation of glutamic acid to form the lactam, pyrrolidone carboxylic acid, which by reduction yields pyrrolidine carboxylic acid, or proline.



Animal experiments[1] have shown that, following administration of *d*-glucosamine hydrochloride, the amino sugar is collected to a relatively large extent by the liver and kidney, where it is slowly decomposed. Kawabe[1] found that incubation with liver tissue *in vitro* for 7 hours caused the decomposition of 28 per cent of added *d*-glucosamine hydrochloride.

Accordingly, a control experiment on myself with 20 gm. *d*-glucosamine hydrochloride having produced no ill-effects, 20, 30 and 40 gm. were given by mouth on three consecutive days, the hæmoglobin value being 90 per cent. No increase of uroporphyrin was observed either immediately or during the succeeding two months, but large quantities of a reddish-brown, green fluorescent pigment appeared in the urine. This pigment was soluble in ether and chloroform, exhibited urobilin-like absorption at 520 mμ, but after reduction with ferrous hydroxide or sodium amalgam failed to give a colour with Ehrlich's aldehyde reagent. It was therefore neither urobilin nor the porphobilin of Waldenström and Vahlquist[2].

That this pigment was not produced by acid treatment of *d*-glucosamine in the urine was proved by addition of amino sugar to normal and porphyric urines, which were then subjected to the same isolation procedure. Pigments so obtained showed no fluorescence.

Two months after the above experiment, the circulating hæmoglobin level had fallen to 50 per cent, with red blood cells numbering 2,070,000 and colour index 1·16. To improve this condition a concentrated liver extract containing iron was given by mouth over a period of seven days (30 ml. per day), when it had to be discontinued. The effect of this treatment was extremely adverse, as it was followed immediately by an attack of migraine, vomiting, sleeplessness and severe constipation lasting three weeks, during which the urinary uroporphyrin excretion reached a peak value of 26·7 mgm. per litre.

There was no evidence of increased blood destruction as indicated by urobilinogen output, and it was concluded that the raised uroporphyrin excretion was associated at that time with increased rate of erythropoiesis and porphyrin synthesis.

## Bacteria Responsible for the Loosening of Wool on Sheepskins

THE sweating process of fellmongering is widely used in Australia, especially for treating merino sheepskins. It depends on the natural loosening of the wool that occurs when the skins are exposed to the air and kept moist for some days. The wool can then be easily removed by 'pulling'.

Investigations of the sweating process in this laboratory[1] have been greatly facilitated by the development of two new experimental methods:

(1) A physical method of following the progress of wool loosening. This involves measurement of the pull in grams weight to remove a staple of wool of which a 2·5 cm. length after scouring and drying weighs 1 mgm. The staples are pulled manually by means of a clip attached to a 250-gm. spring balance, and the average of six values determined for any particular sample of skin is referred to as the 'depilation load'. The depilation load must be practically zero before the wool can be pulled easily.

(2) A method of sterilizing sheepskin and removing the sterilizing agent to permit investigation of the wool-loosening activity of pure cultures of bacteria. The skin sample is immersed for 17 hr. in 0·05 *M* sodium metabisulphite adjusted to *p*H 2, the residual sulphurous acid and its salts are oxidized by immersion for 7 hr. in 0·3 *M* hydrogen peroxide, and the *p*H value at the skin surface is increased to approximately 8 by immersion for 17 hr. in 0·1 *M* sodium bicarbonate. No visible skin changes are produced in the course of this treatment and only a slight normal fall in depilation load was observed during subsequent storage for three days at 25° C. However, rapid wool-loosening occurred after inoculation of the skin with washings from a non-sterile skin or with some pure cultures of the bacteria listed below. This method was only adopted after it had been shown that the acetone-benzol drying and heating method of Chambard and Azémar[2], X-ray irradiation, and treatment with antiseptics such as chlorine, iodine and mercuric chloride were unsatisfactory owing to the production of undesirable changes in the skin tissues, tendering of the wool, or difficulty of removing the sterilizing agent.

By sterilizing sheepskin as described above and measuring the depilation load during incubation at 25° C. after inoculation with pure cultures of bacteria, it was shown that of the seventy-five species and strains of bacteria occurring on sheepskins, comprising forty-seven aerobes and twenty-eight anaerobes, only four were capable of reducing the depilation load to zero within 41 hr. So far as could be ascertained from Bergey's classification[3], they are: (1) An atypical strain of *Proteus vulgaris* (No. 7). (2) An unidentified species of Achromobacter (No. 42). (3) *Flavobacterium estero-aromaticum* (No. 52). (4) An unidentified species of Flavobacterium (No. 28). (The numbers in brackets refer to the system of classification used in this laboratory.)

Confirmation that only four out of the seventy-five species and strains isolated possess wool-loosening activity was obtained by inoculating sterile fœtal lambskin instead of sterilized adult sheepskin. The skin samples used were removed aseptically

from almost full-term fœtuses, as described by Ellis[4].

Observations on the normal bacterial flora of wool roots during sweating have shown that *Proteus vulgaris* (No. 7) is probably the principal sweating bacterium, for although it occurs in relatively small numbers on the wool at the beginning of sweating, it is present in almost pure culture on the wool roots when wool loosening is complete. Sometimes the unidentified species of Achromobacter (No. 42) is also present at the completion of sweating, but then usually in equal numbers with No. 7. The flavobacteria occur rarely on wool roots during natural sweating.

*Proteus vulgaris* (No. 7) may be identical with *Bacillus pilline* isolated from sheepskins by Villon[5], and with the Streptococcus of Schmitz-Dumont[6], since its morphology varies under certain conditions. Similarly the bacilli "d" and "e" described by Wood[7], and "No. 1" and "No. 6" described by Chambard and Azémar[2], may be identical with No. 7 and No. 42 respectively isolated from Australian sheepskins. Owing to the incomplete descriptions, they cannot be identified with certainty.

## Display and Bower-building in Bower Birds

THE recent note on this subject by Marshall[1] is of considerable interest in directing attention to the life-history of a remarkable group of birds. Of particular significance is the apparent correlation between the colours of the objects used by the male for decorating the bower and the more conspicuous colours of the female. If this correlation exists, it can have obvious epigamic value. Marshall studied especially the satin bower bird (*Ptilinorhynchus violaceus* (Viellot)), which prefers blue and green-yellow objects for decoration, and these colours can admittedly be correlated with the blue eyes of the female and the green-yellow of her plumage. But the spotted bower bird, a speckled brown bird with a bright mauve-red neck-tuft, shows preference for green and white objects, the white objects often consisting of bleached bones. Sometimes, with this species, green berries which have been placed in the bower turn red or yellow and are then promptly rejected. Yet another species, Newton's bower bird, with brown and yellow plumage, collects white flowers only. From the facts so far known, therefore, the correlation between choice of colours and plumage does not apparently extend to other Australian bower birds.

The oil-droplets in the cones of the avian retina form inter-occular filters the colours of which vary with the colour and proportion of the oily constituents, and hence there is reason for believing that the spectral sensitivity of birds will vary from species to species. In other words, we are led by physiological reasoning to suspect specificity in relation to colour-awareness in birds, and from this it is a temptation to assume that such specificity must necessarily bear a relation to the plumage colours of the species. So far, however, few convincing experimental findings have been produced to support this view, and the bower birds, representing as they do a *natural* experiment, will amply repay further close and accurate study, the results of which will far outweigh in value any artificial studies on domestic types like the hen and pigeon.

## 'Soil' Mechanics

HAVING read with interest the correspondence in recent issues of *Nature* on the suitability of the expression 'soil' mechanics, I am moved to express the hope that the writers will be more successful than I have been in securing the adoption of a better term.

I remember that the use of the expression 'soil' mechanics dates from an earlier time than that of the First International Congress at Harvard in 1935 (as stated by one correspondent) and that I then made strong representations to friends in the United States about its misleading nature. In reply, I was told that it was already too late to effect a change. Then came the Congress, which served to make the term more widely known and established. Thus it appears that, because somebody had mistranslated Terzaghi's original German expression, we were to be condemned for all time to suffer an inevitable muddle in nomenclature.

When, in 1940, I served as the geological member of the appropriate panel of the Committee on Earth Pressures of the Institution of Civil Engineers, I again protested vigorously against this use, or misuse, of the word 'soil', and suggested in its place 'earth', if the alternative and more precise expression 'unconsolidated rocks' (not 'unconsolidated deposits', which is too restricted in scope) were adjudged too cumbrous. But once more I failed, for 'soil' mechanics was said to be too firmly rooted in engineering literature to be eradicated.

Although we are not warranted in any circumstances in defending the slipshod use of words, the trouble in the present instance lies deeper than the simple question of nomenclature. In my experience, the result of the adoption of the expression 'soil' mechanics is that engineers and chemists who have occasion to consult the literature of 'soils' in this connexion are directed (by way of librarians or bibliographies) to pedological literature and not to the appropriate geological sources of information on unconsolidated rocks—sometimes with unfortunate results.

# REACTION OF HUMAN SERUM ALBUMIN WITH HÆMATIN AND HÆM

By JOAN KEILIN
Molteno Institute, University of Cambridge

IT was shown by Heilmeyer[1] that the pigment in the blood serum of certain cases of pernicious anæmia accompanied by a severe "hæmatin jaundice" or "hæmatinæmia" differs from free alkaline hæmatin in that the absorption band is at about 620 mμ instead of at 610 mμ. As this pigment was also obtained by Heilmeyer[2] *in vitro* by adding hæmatin to blood serum, he concluded that "in serum the hæmatin combines with proteins which are only split off on adding an excess of concentrated alkali. Thus in serum we are concerned with the spectrum of a protein-hæmatin and not that of alkaline hæmatin".

The same pigment was discovered independently by Fairley and Bromfield[3] in the plasma of patients suffering from blackwater fever, which is one of the most dreaded complications of malaria. They described this pigment under the name of pseudomethæmoglobin, showing that it differs from ordinary methæmoglobin (1) in having its absorption band at about 623 mμ instead of at 630 mμ; (2) in not being easily reduced by Stoke's solution; and (3) in not reacting with hydrogen sulphide, sodium azide, sodium fluoride or hydrogen peroxide. Fairley and Bromfield have also shown that it is formed when oxyhæmoglobin is incubated at 40° C. for 24–72 hours with human plasma. In 1938, Fairley[4] obtained this compound by adding alkaline hæmatin to human or simian blood sera; he failed, however, to obtain it with the sera of other animals. Since of all the protein fractions of human serum only albumin would give this compound, Fairley changed its name from pseudomethæmoglobin to methæmalbumin. On reduction with sodium hyposulphite a compound was formed which Fairley[4,5] described as hæmalbumin, characterized by two diffuse absorption bands at 573 mμ and 530 mμ which after standing a few minutes were replaced by one very diffuse band at about 574 mμ.

In addition to cases of blackwater fever, where the presence of methæmalbumin was confirmed by Foy and Kondi[6], this pigment was found by Fairley and Bromfield in cases of nocturnal hæmoglobinuria, incompatible transfusion and pancreatic cyst fluid (see Fairley[4]). It is interesting to note that in blackwater fever it is found in the plasma, where it is accompanied by oxyhæmoglobin, but not in the urine, which contains oxy- and methæmoglobin.

The main object of the present investigation was to determine the nature of the compound described by Heilmeyer and Fairley. For reasons which will be given later on, the ferric and ferrous forms of this compound will be referred to as hæmatin-albumin and hæm-albumin respectively.

## Preparation of Hæmatin-albumin

Hæmatin-albumin was prepared as follows: 20 mgm. hæmin are dissolved in 2 ml. 0·1 $N$ caustic soda and made up to 25 ml. with water. To 1 ml. of this solution are added 2 ml. of human serum, human plasma or the albumin fraction prepared from this plasma. The absorption spectrum of the compound thus obtained, together with those of alkaline hæmatin and acid and alkaline methæmoglobin, were determined with the Hilger-Nutting spectrophotometer. Fig. 1 shows that the absorption spectrum of alkaline hæmatin in human serum bears a much greater resemblance to that of free alkaline hæmatin than to those of methæmoglobin, especially as it should be compared not with acid but with alkaline methæmoglobin. As albumin seems to be the only serum protein which gives this compound, hæmatin-albumin is a more appropriate name for it. Moreover, as Fairley and Bromfield[3] have already shown, this compound, unlike methæmoglobin, does not combine with hydrogen sulphide, sodium azide, sodium fluoride or hydrogen peroxide. The absorption spectrum of hæmatin-albumin also differs greatly from that of a parahæmatin, which can be obtained by treating hæmatin with denatured serum proteins.

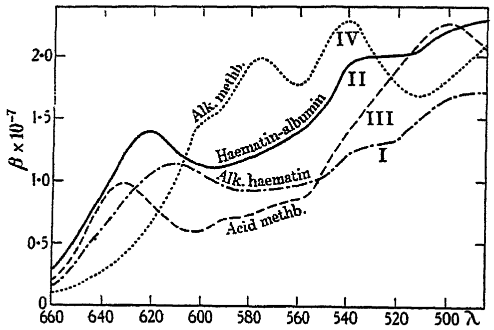

Fig. 1. Absorption spectra of: alkaline hæmatin (I); hæmatin albumin (II); acid methæmoglobin (III); and alkaline methæmoglobin (IV). In all figures the ordinate represents the absorption coefficient $\beta = \frac{1}{cd} \ln \frac{I_0}{I}$, where $c$ is concentration of hæmatin in gram-atom of iron per ml.; $d$ is length of tube in cm.; $I_0$ and $I$ are intensities of the incident and transmitted light respectively. The abscissa represents wave-length in mμ.

*Hæm-albumin.* When hæmatin-albumin is reduced with sodium hyposulphite, the colour of the solution turns from reddish brown to a deep red and its absorption band at 623 mμ is replaced by two bands, α at 570 mμ and β at 540 mμ, the α-band always being much stronger than the β-band. This compound can also be obtained by the addition to hæm of human serum albumin, but not by the addition of any other serum protein fraction. The absorption bands of hæm-albumin, as shown in Fig. 2, are much stronger than those of the free hæm, but much more diffuse and lying nearer the red end of the spectrum than the sharp bands of hæmochromogens obtained from hæm and denatured serum proteins. When human plasma or serum is added to hæm, the first change which is usually observed is the appearance of a very small amount of a hæmochromogen with its characteristic bands; these, however, soon disappear and are replaced by the bands of hæm-albumin. The very small concentration of hæmochromogen which occasionally persists obliterates with its α band the clear space separating the α and β absorption bands of hæm-albumin. It is difficult to say whether this hæmochromogen is formed by the native serum albumin itself, as a transient intermediary stage leading to the formation of hæm-albumin, or by traces of a denatured protein present in the solution.

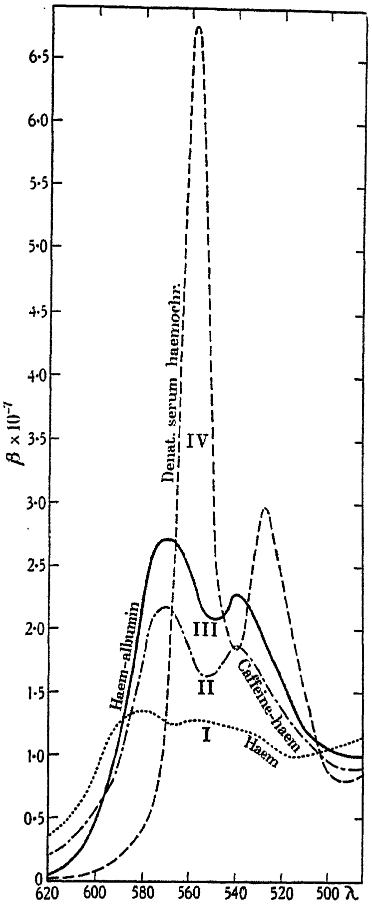

Fig. 2. Absorption spectra of: hæm (I); caffeine hæm (II); hæm-albumin (III); and denatured serum hæmochromogen (IV); $\beta$ as in Fig. 1; the heights of II and III vary to a certain degree according to preparation.

## Nature of Hæm-albumin

The only hæm derivative which bears a strong resemblance to hæm-albumin is caffeine-hæm, which has recently been described (J. Keilin[7]). Both compounds are of the same colour, and the similarity of their absorption spectra is clearly shown in Fig. 2. In the case of caffeine-hæm, it has been shown[7] that caffeine is linked not to the iron but to the porphyrin alone of the hæm molecule, which suggests that in hæm-albumin the protein is also combined with the porphyrin alone. This is strongly supported by the facts that caffeine[7], native globin (Hill and Holden[8]) and "serum proteins" (Haurowitz and Waelsch[9]) form with the free alkaline porphyrins characteristic and spectroscopically recognizable compounds, while among the serum proteins only albumin will react in this way. Finally, by diffusion in gelatine gel and by cataphoresis methods, Gildemeister[10] was able to show that the endogenous coproporphyrins I and III are strongly bound only to the albumin fraction of serum.

## Reaction of Hæm-albumin with Carbon Monoxide

On passing carbon monoxide through a solution of hæm-albumin, its absorption spectrum changes to that of carbon monoxide hæmochromogen, which differs from that of carbon monoxide hæm or carbon monoxide caffeine-hæm in the position and relative height of the two absorption bands (Fig. 3). In hæm-albumin treated with carbon monoxide, the protein therefore appears to combine with the iron of hæm.

It is not surprising that hæm may fail to give a hæmochromogen and yet may form a carbon monoxide hæmochromogen under the same conditions, since it is known that the iron of carbon monoxide hæm has a much greater affinity for nitrogenous compounds than the iron of free hæm. It is, however, impossible to say whether the protein component of this carbon monoxide hæmochromogen is the native serum albumin or a denatured protein present in very small concentration.

It can be said in conclusion that proteins may form with hæm ($Fe^{++}$) three types of compounds: (1) Hæmochromogens: usually given by a denatured protein which is linked with the iron of hæm. (2) Hæm-albumin: given by a native protein linked only to the porphyrin of hæm and forming a compound analogous to caffeine-hæm. (3) Hæmoglobins: where the protein is combined with both the porphyrin and the iron of hæm.

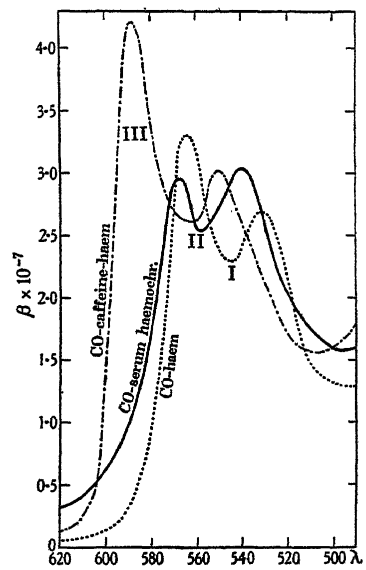

Fig. 3. Absorption spectra of: carbon monoxide hæm (I); carbon monoxide serum-hæmochromogen (II); carbon monoxide caffeine-hæm (III); $\beta$ as in Fig. 1; the heights of I and III vary according to their dispersion but the form remains the same.

I wish to thank Dr. E. F. Hartree for the curves of acid and alkaline methæmoglobins and for the preparation of a pure sample of human serum albumin.

# COLLAPSE OF DETERMINISM

AT the thirty-first meeting of the Indian Science Congress, which met in Delhi in January 1944, the Congress president, Prof. S. N. Bose, discussed "The Classical Determinism and the Quantum Theory", showing how "physicists have gained knowledge but lost their faith". This was supplemented in the Section of Mathematics and Statistics by B. M. Sen, president of that Section, in his address entitled "The Fundamental Equations of Quantum Mechanics". It is difficult to do justice to this without mathematical symbols, so the following article will be based mainly on Prof. Bose's more general treatment.

Classical physics may be said to have begun with Newton. His laws of motion and theory of gravitation gave an explanation of planetary motion which was so satisfactory that it seemed to provide an infallible means of predicting the motion of the solar system. Laplace went so far as to assert that if a sufficiently vast intellect knew the mass, position and velocity of every particle of the universe at any one instant, and the forces acting on them, then "nothing would be uncertain for him; the future as well as the past would be present to his eyes".

It was difficult to fit the phenomena of light into this scheme, since the discovery of interference had shown that light moves like waves rather than like particles. But Maxwell overcame this difficulty by developing Faraday's ideas about the ether. Newton's absolute space was no longer to be regarded as empty, but as a medium possessing energy and momentum, capable of being strained and transmitting waves. This theory was later extended to explain also X-rays, radio signals, and the $\gamma$-rays emitted by radium. Maxwell's electromagnetic theory was extended by Lorentz into a theory of electrons. The modifications in the Newtonian scheme had left it stronger than before. Almost everywhere was seen the reign of exact laws. It was true that in thermodynamics physicists had to make shift with laws that applied only to large aggregates, but no one doubted that these were derivable by averaging from exact equations which were too numerous to be conveniently considered individually. The derivation of these averages contained the term probability or chance, but it was always pointed out that really there was no such thing, and that every occurrence could be predicted if all the circumstances were known. It was characteristic of the eighteenth century, the 'age of reason', that Voltaire should assert that "Chance is a word void of sense: nothing can exist without a cause", and Linnæus that "Nature does not proceed by jumps".

These beliefs were rudely shaken by the quantum theory. In 1900 Planck, puzzled by the phenomena of heat radiation, made the revolutionary suggestion that the emission of energy is discontinuous. Soon afterwards Einstein made a similar suggestion about the photo-electric effect. Bohr explained the spectra of hydrogen and other atoms by postulating that an electron must pass discontinuously from one orbit to another. These postulates were empirical, put forward so as to lead up to the results of experiment. They succeeded in this, but at the cost of abandoning the established laws of mechanics and electrodynamics. What seemed a greater break with tradition was called for by the theory of relativity, but in fact this theory does not reject causality. It is true that it denies the existence of absolute time and absolute space, but it sets up a new set of absolute laws in space-time which are independent of all axes of reference. Einstein's success in explaining the slight discrepancy in the motion of the planet Mercury, and in predicting the apparent displacement of stars during a solar eclipse, struck the imagination of the public, but really it is quantum theory that clashes fundamentally with classical physics.

At one time there were hopes of a reconciliation through Schrödinger's wave mechanics, but it turned out that the waves in question are only mathematical fictions. They are excellent as a means of calculation, as they can be treated by the familiar methods of differential equations instead of by the unfamiliar matrices of Heisenberg or Dirac's algebra of observables. However, all three methods are equivalent, and all lead to the same startling conclusion, Heisenberg's Principle of Uncertainty. This shows that if we measure the position and momentum of a stream of electrons, the more accurately we determine the position the less accurately can we determine the momentum, and conversely. Some think that this merely expresses the obvious truth that every experiment interferes to some extent with the phenomena we attempt to measure. Others go further, and interpret the principle to mean that we cannot predict the motion of a single particle exactly, owing to the slight variation of the forces on it caused by atomic structure, although we can obtain statistical laws which hold for the average motion of a large number of particles. But a third interpretation go[es] so far as to claim that the existence of causality [is] disproved. Von Neumann claims to have demonstrated that the results of the quantum theory cannot be obtained by averaging any exact causal laws.

Some philosopher-physicists welcome these conclusions, as giving us a hope of escape from the tyranny of an iron law of causation, and assuring freewill to mankind as well as to electrons! However, the majority of physicists regard causality as essential to science, and are hoping to establish a unified theory that will once again reunite all our knowledge into exact causal laws. While the matter is still unsettled, we should do well not to insist on imposing our preconceived ideas upon Nature, but let them evolve and adjust themselves to our growing, if somewhat unmanageable, knowledge of reality.

H. T. H. PIAGGIO.

# THYROXINE: ITS BIOSYNTHESIS AND ITS IMMUNO-CHEMISTRY*

THE suggestion that thyroxine might be formed in Nature from tyrosine through the stage of diiodotyrosine was made at an early stage of the elucidation of the chemistry of thyroxine, and was made more probable when the constitution of the latter was finally determined. Over a number of years several pieces of evidence, all indirect in character, were brought forward in support of this biogenetic hypothesis, which thus came to be generally accepted.

Recently two lines of direct evidence have become available which seem to place the matter beyond doubt. In the first place, the transformation of diiodotyrosine into thyroxine has been effected by purely chemical methods of a character which make

* Abstract of the Croonian Lecture of the Royal Society delivered by Dr. C. R. Harington, F.R.S., on July 13.

it possible to formulate a theory of the chemistry of the process involved. Secondly, by the application of modern biochemical technique, the actual synthesis of thyroxine from diiodotyrosine has been demonstrated in surviving thyroid tissue *in vitro*. The latter type of experiment incidentally offers an opportunity for the analytical study of the action of substances such as thiourea, which inhibit thyroid activity supposedly by interfering with the biosynthesis of the hormone.

Accepting the mechanism of biosynthesis of thyroxine as being satisfactorily established, we are left with two outstanding problems. Is thyroxine itself the actual circulating thyroid hormone, and, if so, by what mechanism does it exercise its effect in the periphery? To the second of these questions no answer can yet be given. Evidence regarding the first is conflicting, and in the attempt to obtain a definitive answer an approach has been made along a new line which raises matters of some general interest. The method is based on the theory, deduced from the known facts of immunological chemistry, that an antigen of which the determinant group is a physiologically active substance should give rise to an antiserum capable of inhibiting the characteristic activity of this substance. Application of this idea to the problem of thyroxine involved the development of a new technique for building up artificial antigenic complexes. Such a complex containing thyroxine as the determinant group has proved to be able to give rise to an antiserum which can inhibit the physiological action both of a protein containing thyroxine, such as thyroglobulin, and of thyroxine itself. The latter observation, together with extension of the experimental method to an entirely different compound, favours the hypothesis that thyroxine itself is in fact the actual circulating thyroid hormone.

## INCIDENCE OF RICKETS IN GREAT BRITAIN

DURING the six weeks from mid-January to the end of February 1943 the British Pædiatric Association carried out a combined clinical and radiological investigation into the frequency of rickets in twenty-three areas of Britain and Ireland*. Out of a total of 5,283 children aged 3–18 months, 106 only were reported to show radiological evidence of rickets. Dr. Percy Stocks, who analysed the returns, concluded that the incidence of rickets, diagnosed radiologically, was 2·5 per cent before six months, 4 per cent during the first year and negligible after the first year. The incidence was highest in Ireland and lowest in South England. In Watford and St. Albans no case was detected even by clinical methods. There is no evidence of any increase in the incidence or severity of rickets during the War. In some of the cities of north England, older children with deformities due to severe rickets may still be seen, whereas the cases found in this investigation were slight and free from any gross deformity. It may be inferred that severe rickets was more common a few years ago.

Two points stand out. First, the number of cases diagnosed by clinical methods was nearly ten times the number diagnosed radiologically. Even the three radiologists who examined the films differed in their interpretations. Obviously, we do not yet know what constitutes evidence of slight rickets. But this disagreement is itself evidence of the mildness of the disease, for there is no mistaking severe rickets.

Secondly, 85·5 per cent of the babies that were considered to have rickets on X-ray evidence had had some form of treatment with vitamin D. On this point the report is disappointing. Examiners were supposed to find out what preparation was used, when dosage began, and the daily dose given; but analysis in terms of the duration of vitamin D prophylaxis and the dosage was not attempted, and the nature of the preparations used is not mentioned in the report. It is little use saying that "scientific evidence has clearly shown that adequate vitamin D administered in an adequate dosage and in a suitable form will prevent rickets", and that "a common cause of rickets is the popular cod liver oil-and-malt", without inquiry into the reasons why 77 out of 4,317 babies who were given vitamin D got rickets. The fashion of handing over the results of an investigation for mechanical analysis by a statistician who may not appreciate the importance of the problems that may be involved has its disadvantages.

## MODERN ASPECTS OF INORGANIC CHEMISTRY

THE presidential address by Prof. R. C. Ray to the Chemistry Section of the Indian Science Congress at Delhi dealt with some aspects of modern inorganic chemistry. After mentioning that research in inorganic chemistry had declined towards the close of the nineteenth century, mainly because of the very rapid development of organic chemistry and the rise of physical chemistry, he pointed out that there are very many new aspects of the subject now being developed.

Prof. Ray went on to describe some interesting developments. Compounds of the inert gases with water, boron fluoride and phenol have been obtained, and compounds with metals such as mercury, and iodine, sulphur and phosphorus are described. A subject which has been fully studied, particularly by Stock, Wiberg, Bauer and others, is the chemistry of the hydrides of boron and related compounds, which are also of great interest in relation to the electronic theory of valency. In this field, Indian workers have made important contributions, particularly Prof. Ray and his pupils, who have also worked on the chemistry of co-ordination compounds, glass and hydrides of metals such as nickel.

Nickel forms two hydrides, $NiH$ and $NiH_2$, and cobalt forms analogous compounds, the heats of formation being comparable with those of the salt-like hydrides of the alkali and alkaline earth metals. The heats of formation of hydrides of some rare-earth metals, zirconium, tantalum and titanium, generally regarded as interstitial compounds, are also of the same order, this suggesting that there can be little difference in the nature of the chemical bond in such substances as zirconium hydride and barium hydride, with nearly equal heats of formation.

Prof. Ray considers that there has probably never been a time when the prospects of inorganic chemistry were so promising as they are to-day, when new methods in physics, physical chemistry and organic chemistry are available.

# EXCAVATIONS AT TRES ZAPOTES, MEXICO*

AN account has now been issued of the first season's work of the joint expedition of the National Geographic Society and the Smithsonian Institution to Tres Zapotes. The site is a large one, and the remains consist of earth mounds with little or no masonry. The deposits are tentatively assigned to three periods, Middle Tres Zapotes *A* and *B* and Upper Tres Zapotes. This nomenclature depends on the existence of a Lower Tres Zapotes horizon, discovered during the work of the second season.

The Middle *A* and *B* deposits were not found in superposition, but there is little doubt about their relative age. On one site, Upper Tres Zapotes was found overlying Middle *A*, but separated from it by 6 ft. of sterile deposit.

Middle Tres Zapotes *A* is associated with large numbers of hand-made, solid clay figurines of archaic type, and although there is always a possibility that they are a late survival in a marginal area, the balance of the evidence favours an early date. The Middle *B* period contains uncremated burials in large ollas. It is marked by the first appearance of painted pottery, and there are contacts with many other cultures, conspicuous among which is the Maya Old Empire. The Upper period contains cremated burials in covered bowls, and the pottery is of great complexity. A curious feature of the site is the paucity of Aztec remains.

The work described was admittedly exploratory and many problems are left unsolved. Some of the results of the work of the second season were already available when it went to press, so it seems a pity that publication was not delayed until they could be incorporated and a fuller picture given. The illustrations are good and clear, but should as a matter of routine have been provided with a scale in every case. The same criticism applies in a greater degree to maps 2 and 3, and to the section which is, rather curiously, designated "Map 6".

G. H. S. BUSHNELL.

# FORTHCOMING EVENTS

### Tuesday, July 25

QUEKETT MICROSCOPICAL CLUB (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Exhibition of Specimens and Discussion.

# APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER IN EXPERIMENTAL PHYSIOLOGY—The Registrar, The University, Sheffield (July 28).

LECTURER IN THE ELECTRICAL ENGINEERING DEPARTMENT—The Registrar, Technical College, Sunderland (July 29).

JOHN RANKIN CHAIR OF GEOGRAPHY—The Registrar, The University, Liverpool (July 31).

W. H. COLLINS PROFESSORSHIP OF HUMAN AND COMPARATIVE PATHOLOGY—The Secretary, Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C.2 (July 31).

SENIOR LECTURESHIP IN THE DEPARTMENT OF METALLURGY of the University of the Witwatersrand—Dr. W. Cullen, 4 Broad Street Place, London, E.C.2 (July 31).

PRINCIPAL OF THE MID-ESSEX TECHNICAL COLLEGE AND SCHOOL OF ART, Chelmsford—The Chief Education Officer, County Offices, Chelmsford (August 5).

ASSISTANT LECTURER IN METALLURGY—The Acting Registrar, The University, Leeds 2 (August 12).

ASSISTANT PHYSICIST to the Sheffield Radium Centre—The Secretary, Sheffield Radium Centre, Royal Infirmary, Sheffield 6 (August 12).

BIOLOGIST at the West Midland Forensic Science Laboratory at Birmingham—The Establishment Officer, Room 320, Home Office, Whitehall, London, S.W.1 (August 12).

LECTURER IN PHILOSOPHY—The Very Rev. the Dean, Christ Church, Oxford (October 15).

LECTURER IN PHYSIOLOGY—The Principal, Nonington College of Physical Education, Bromsgrove.

ASSISTANT PHYSICIST (with experience of the Physics of Radiotherapy)—Mr. S. Clayton Fryers, General Infirmary, Leeds 1.

SCIENTIFIC ASSISTANT (Science Degree) and TECHNICAL ASSISTANT (Arts Degree)—Imperial Bureau of Animal Health, Veterinary Laboratory, Ministry of Agriculture, New Haw, Weybridge, Surrey.

## VETERINARY EDUCATION IN GREAT BRITAIN

IN a leading article in *Nature* of January 8, 1944, the existing constitution and powers of the Royal College of Veterinary Surgeons, and the system of training and examination of British veterinarians was outlined. The key position of the veterinarian in the future, invested, as he must be, with the care of animals upon which our meat, egg and milk supplies depend, was then emphasized, and the interdependence of veterinary medicine and the agriculture from which we derive other vital food supplies was also pointed out. The desirability of a much closer association between the veterinary and the medical professions was also discussed. In the same issue of *Nature*, reference was made to a paper by Major J. M. Smith, in which he made very clear the vital part played by the veterinarian in the affairs of the British Colonies.

A Committee on Veterinary Education in Great Britain was appointed in 1936 by the Government, and issued its first report in 1938. In 1943 the same Committee was asked to reconsider its first recommendations, because, as the Minister of Agriculture wrote to Dr. T. Loveday, vice-chancellor of the University of Bristol, who is its chairman, there have been since 1938 great changes in the position and prospects of agriculture in Great Britain. The Government, wrote Mr. Hudson, intends to maintain after the War a healthy and well-balanced agriculture as an essential and permanent feature of its national policy; and livestock, especially dairy herds, will need adequate care. The best possible training for the veterinarian of the future, continued Mr. Hudson, is therefore of vital importance to agriculture, and substantially greater numbers of veterinarians will be required. The Committee has in consequence met again, and its second report has now been issued (London: H.M. Stationery Office, 6*d*. net), and will presumably go before Parliament for discussion.

The Committee emphasizes that its revised recommendations are intended to secure, not merely an efficient system of training for the veterinarian, but also what it considers to be the best possible training. It also emphasizes that the revised recommendations are based on the assumption that British agriculture will, in fact, be maintained in a healthy and prosperous condition, "and will not be allowed to fall back into the state of uncertainty and depression which progressively prevailed between 1920 and 1939". The revised recommendations do not supersede those of the Committee's first report, except in certain important and possibly controversial particulars; and the main conclusions of the first report are printed in Appendix I for comparison. A point strongly emphasized by the Committee is the urgent need for inquiry into the growing evil of unqualified veterinary practice, a recommendation to which effect has just been given (*Nature*, July 22, p. 111).

There should not be—indeed, there is not—in the mind of anyone who has given even a thought to the cost of animal disease in Great Britain alone, any doubt of the need for veterinarians, or of the financial

saving which expansion of their work could effect. Appendix III of the report gives details of the national loss due to various diseases of farm livestock. The Committee estimates that the total cost to the nation is not less than thirty million pounds a year, and rightly considers that the bulk of this loss is preventable, but only if much more money is spent on veterinary training.

Dealing with the future demand for veterinarians, the Committee revises its earlier estimate that about 150 veterinarians would be required annually between 1938 and 1942 and 115 afterwards. Actually 571 veterinarians qualified in the years 1940, 1941 and 1942, without causing unemployment in the profession. The Ministry of Agriculture and Fisheries, bearing in mind its plans for the future expansion of the State veterinary service and the Government's use of the services of private veterinary practitioners, now estimates a demand for 220 veterinarians a year for about ten years, with a possible reduction to 150 a year later. The reasons given by the Committee for the increasing demand for veterinarians are the increasing appreciation by the farmer and the public that the veterinarian is the guarantor of the nation's food supply; the fact that the Government seems to be aiming at a quarterly examination by veterinarians of every dairy herd in the country (it is estimated that about 2½ million dairy cattle, which is about 80 per cent of all the dairy cattle in Great Britain at present, get no regular veterinary supervision); extension of veterinary supervision of meat production and of its control on the way to the market; and increases in the requirements of owners of riding horses and small animals. Most of the witnesses consulted agreed to this figure of 220; but others, including the Royal College of Veterinary Surgeons, hesitated to do so, partly because they feared that the Government's present policy would not be carried on and partly because they feared that the unqualified practitioner might reduce the work of qualified men.

The Committee does not think that qualified men from Eire will come over to practise in Great Britain in sufficient numbers to affect the demand, and it recalls that most of the veterinarians practising in British Colonies are trained in Great Britain. This Colonial demand will, the Committee thinks, increase rather than diminish, because, as the control of the major diseases of livestock in the Colonies, which has occupied and is now occupying the attention of Colonial veterinarians, becomes established, other diseases which have been masked by these major diseases will need attention, and these are likely to require more men for their control. Because the progress of pastoral Colonial peoples depends largely upon adequate production of dairy and other livestock products, this branch of the work of the veterinary profession is likely to become increasingly important. The Committee's recommendations are therefore framed on the estimate of 220 veterinarians a year for ten years, and it sees no reason at all why this demand should fall to 150. It is suggested, in fact, that the figure 220 may prove to be too low. In support of this view, the report includes a table based on information supplied by the Allied Post-war Requirements Bureau, which shows that the number of veterinarians per million of the large domestic animals is 94·4 in Great Britain, 98·8 in France, 123 in Norway, 140 in the Netherlands, 148 in Denmark, 149 in Germany, and 247·8 in Switzerland. In the United States the corresponding figure is only 60, but much farm stock in that country is kept under ranch conditions; further, reforms in veterinary education and increases in the numbers of veterinarians are now being urged and planned. The table indicates that the number of veterinarians per million of the population in the United States is twice as great (109) as it is in Great Britain (50·2) and the United States figure compares favourably with the corresponding figures cited for other European countries.

The rest of the report deals with the number and location of the veterinary schools, the functions of the Royal College of Veterinary Surgeons, the licence to practise, the association of veterinary training with the universities of Great Britain and with finance. The training of 220 veterinarians a year cannot, the Committee decides, be accomplished by the expansion of the existing four veterinary schools at London, Edinburgh, Liverpool and Glasgow. Eire and its veterinary school at Dublin are not considered. The ideal size for a veterinary unit is, the Committee concludes, one which will provide thirty graduates a year, and all the universities consulted agreed to this figure. The Liverpool school cannot expand beyond this, which it now achieves. The existing Glasgow College is inadequate. If thirty men a year are allocated to this school, which would become an integral part of the University of Glasgow, the London and Edinburgh schools would have to produce 160 graduates a year between them, which would mean about 1,000 students in these two schools combined. The Committee considers that this is too many. Complaints of overcrowding are already universal, and the Committee agrees that they are well founded. It suggests that the number of students at the London school should be limited to 325, and at the Edinburgh school to 275, and that the field stations attached to each school, recommended in the Committee's first report, and again emphasized in this second one, should relieve the pressure on these schools by providing most of the clinical training. London and Edinburgh should then be able to supply a hundred veterinarians a year.

Provision would then be required for sixty more, and the Committee proposes the establishment of two new colleges, one at Bristol and one at Cambridge. There would thus be six veterinary schools in Great Britain, each with a field station and preferably with a hospital for large animals. Veterinary students would receive farm pupilage for not less than six months in the care of normal livestock and also would spend at least six months with a practising veterinarian. There would be provision, in the normal estimates of each school, for continuous research, and bursaries and graduate scholarships would be provided. It is rightly emphasized that these should be of sufficient value to enable the recipients to

take a full part in university or college life. Private endowment of veterinary education and the work of the Veterinary Educational Trust are also commended.

The reasons for the selection of Cambridge and Bristol as the sites of these two new centres need not be set out in detail here. At Cambridge the veterinarian would be in contact with experts in all the branches of science and the arts, and also with the various agricultural institutes there. At Bristol a veterinary college would, the Committee thinks, be well placed to serve the area south and west of a line drawn between Aberystwyth, Worcester, Swindon and Weymouth. A veterinary school in Wales was considered and urged by the Welsh Council of Agriculture; but the Committee felt that each veterinary school should be in close touch with a large and important grazing district, should be able to establish a field station within easy reach, should have suitable accommodation for the pre-clinical years, should be in a centre possessing good medical and agricultural schools and should be remote from other veterinary schools. Although Cardiff and Aberystwyth both fulfil some of these requirements, the Committee concluded that Bristol could best serve south-western England and central and south Wales, while Liverpool could serve north Wales. Not everyone will agree with the Committee's rejection of the claims of Wales to its own veterinary school. The Committee says that, if the demands of the future require more centres, the claims of Wales will have to be considered. Many will think that they should be satisfied now, one reason being that Wales, like Scotland, presents rather special veterinary and agricultural problems which should be studied at such a Welsh centre.

The requirements detailed by the Committee for the choice of sites for veterinary schools are, however, intimately bound up with one of the most important of the Committee's recommendations. This is the Committee's view that the best possible training for the veterinarian can only be obtained by persuading the universities to undertake the responsibility for it. This recommendation is an extension of the recommendation in the Committee's first report that there should be a close connexion between veterinary education and the universities. It involves far-reaching changes, some of which are not, as recent correspondence in *The Veterinary Record* shows, acceptable to many members of the veterinary profession. The Committee's ideal is that veterinary schools should become parts of universities in the same sense as medical schools. This is already so in Liverpool. The Committee is satisfied that the following conditions should apply to all university schools of veterinary medicine. The necessary money should be provided by the State; the degree in veterinary medicine given by the university should become a registrable qualification; and the university should have a measure of control over the instruction given, and over the university examinations held, similar to that "generally exercised in the case of medical degrees".

While the Committee "favours the idea" that the universities concerned should establish new faculties of veterinary medicine, it does not make any definite recommendation on this point, because "so much depends on the conditions prevailing at each individual University". Many will regret the lack of decision in this matter. If veterinary education is to be undertaken by the universities at all, it must certainly be given, from the very beginning, an equal status with medicine, agriculture or any other university study which constitutes a faculty. It would be emphatically insufficient, for example, to create a department of veterinary medicine within, or subordinate to, any other faculty. The veterinary profession can only be given its legitimate place in any university by the creation of a faculty of veterinary medicine of full status, the affairs of which would be governed, like those of other faculties, by the veterinary staff in co-operation with other university teaching officers. In no other way would it be possible for the veterinary teacher as well as the veterinary student to take their full part in university life and to experience its full effects. By administering and teaching in a full veterinary faculty the veterinarian would, moreover, be in the best position to introduce effectively into the university those new problems and new spheres of work which could be such valuable additions to university studies. This contribution which veterinarians can bring to the universities is too easily overlooked. It has a very real national importance and no university can afford to neglect it.

While it is clear that the Committee desires the creation of faculties of veterinary medicine of independent status, it is no less clear that it emphasizes its further recommendation that university degrees in veterinary medicine shall be registrable qualifications. There is a lack of clarity in the report on this point which requires elucidation. The Committee recommends that university degrees in veterinary medicine shall be registrable by the Royal College of Veterinary Surgeons and by that College alone; and it also recommends that the Royal College shall continue its own examinations and shall continue to grant the diploma of M.R.C.V.S. on the results of these examinations, which would presumably be held only in those existing veterinary colleges which do not, for one reason or another, become constituent parts of universities. There would thus be two possible veterinary qualifications—a university degree in veterinary medicine, and the diploma of M.R.C.V.S. granted only by the Royal College of Veterinary Surgeons on the results of its own examinations. The Committee's recommendation is that the Royal College of Veterinary Surgeons should be the only body legally empowered to register either or both of these qualifications, and to grant a licence to practise veterinary medicine. The recipient of a university degree in veterinary medicine would therefore have to register with the Royal College of Veterinary Surgeons, just as the recipient of a university degree in medicine or surgery must place his name on the Medical Register before he can practise.

It would further be necessary, the Committee thinks, to create a body independent of the univer-

sities which would be empowered to secure a minimum standard of qualification to practise veterinary medicine. It is proposed that the Council of the Royal College of Veterinary Surgeons should be given this power. The College would therefore control both the education of veterinarians and their licence to practise. Its constitution would be widened and it would be given powers similar to those granted to the General Medical Council by the Medical Acts of 1858 and 1886, the relevant portions of which are quoted in Appendix VI of the Committee's report. These Acts would empower the new Council of the Royal College of Veterinary Surgeons to appoint inspectors who would have the right to attend, and report on, the examinations held at any centre, and to ask for details of the courses of instruction provided. If either these courses or the examinations were not considered adequate, the Council of the College could report to the Privy Council, which could declare that such courses or examinations should not qualify for a registrable qualification in veterinary medicine. The new Council's authority would also extend to veterinary schools which are not parts of universities.

It would thus seem that the Royal College of Veterinary Surgeons would retain all reasonable control of the profession. Some veterinarians have said that the proposals of the Committee involve the relinquishment by the College of the sole control over the educational standards of the veterinary profession in Great Britain which it now exercises; but other veterinarians have replied to this that, in actual fact, the College does not at present exercise this control. It controls only the examinations, and has no control over the instruction given in the existing veterinary colleges, nor any over the time which is given to the study of individual subjects in them.

Objections have also been raised to the Committee's proposal to bring into the new Council of the Royal College of Veterinary Surgeons certain persons who are not veterinarians. Here it should be emphasized that precisely four, and four only, of the thirty-three members of the new Council need not be veterinarians. The Committee does not, let it be noted, say that these four must not be veterinarians. They are to be appointed by the Crown; and no doubt the Crown will appoint, if not veterinarians, then men who have shown themselves to be sympathetic to the veterinary profession or to have contacts with it which have given them an understanding of its problems and aspirations. The profession itself is, moreover, to be given the majority vote in the new Council; for seventeen of the thirty-three members would have to be freely elected by the profession precisely as the whole Council is now elected. The other twelve would be nominated by the universities and the veterinary colleges which would teach and grant the single registrable qualification. Twenty-nine members of the new Council would be veterinarians and a majority of the whole Council would have to be freely elected by the profession. If such a Council could not safeguard every vital interest of the profession, then the profession itself would alone be to blame. It is worth remembering, also, that the report of this Committee is not a series of edicts from which there is no appeal. It is a number of recommendations based on evidence taken from veterinarians themselves and from teachers of veterinarians, as well as from educational experts all over Great Britain; and these recommendations are put forward for calm discussion in Parliament and elsewhere.

The Committee was specifically asked to devise plans for the best possible training for the veterinarian, having regard to the anticipated expansion of the profession, and it believes that university training alone can effect this. There will be few who will not agree with this view. Many veterinarians are already taking university degrees of one kind or another as well as their veterinary training. This means, as the Committee points out, that they have to take two or more courses, with the corresponding examinations, and must thus waste much time. One result, however, is that increasing numbers of veterinarians are learning by experience the advantages of university life, and most of them will be strongly in favour of the Committee's insistence on university education. They are by no means uncritical of the universities. No progressive mind is. Most people who have given any thought to the universities desire reforms of one kind or another. It is, in fact, one of the most valuable results of university education that it teaches men the folly and sterility of stagnation and satisfaction.

Veterinarians, moreover, like all men of science, must, as members of scientific research teams, experience that cultural effect of practical scientific work which teaches men to sink their own desires and differences and to pull their full weight for the achievement of a common aim. They may think that this is enough; or even that it is better than a university education. But surely the best university education is essentially an extension of this spirit, not only into the non-scientific world, but also into the social unit, the nation and finally the world. Men experiencing it cannot fail to become, as the Committee suggests, better men. "Universities," wrote Dr. John Murray in the *Sunday Times* (May 7, 1944), "can only vivify each new generation by witnessing to the common body of culture"; and he rightly pointed out that, in an age of specialism, we must compensate for specialism by common study carried out in a community. The logic of events, he writes, is making the universities the meeting ground of the youth of Britain and of every other land; it is making them "agencies of mutual understanding, organs of a world spirit of amity and conciliation". The veterinarian should be included in this Parliament of Youth, for his work has a vital place in the development of civilization. Dr. Murray thinks that the future of the universities may lie, not in great cities, but in small ones, in old and historic places, in the countryside where there is continuity with the past, in "places such as Oxford was and Cambridge still is". It is not irrelevant to add to these the Exeter from which Dr. Murray writes, and where he presides over an educational community which draws to its

happy atmosphere students from all over the world. It seems a pity that this College, situated as it is in the middle of one of the greatest agricultural districts of England, cannot be given a part in the training of the veterinarians whose services that district must have. Would it not be possible, for example, to link it with the new centre at Bristol in some form or other ?

Another aspect of the Committee's report remains for comment. The Committee adopts, on more than one page of its report, what some will consider to be an insufficiently firm attitude to the universities. The Committee, for example, "strongly urges" the universities giving registrable veterinary qualifications to include practising veterinarians among their external examiners, and to consult the Council of the Royal College of Veterinary Surgeons when they are appointing them. The College, of course, insists on the inclusion of veterinary practitioners as examiners in the clinical subjects, and many will think that the universities should be plainly told that they must establish a rule so obviously essential. Elsewhere the Committee says that it is "encouraged to believe" that one of the universities concerned "might be prepared to establish a School of Veterinary Medicine" such as the Committee proposes and to grant a degree in veterinary medicine, subject to the conditions which have been mentioned above. Of another university the report says that the Committee understands "that the university would not be adverse in principle" to its proposals. The position at another university centre is described as "exceptional". The remaining two universities have, however, expressed their willingness to carry out the Committee's proposals. There would thus appear to be a need for a reminder that all universities, jealous as they must be of their independence, also have a public duty in a matter of such national importance as this.

There is a spirit abroad among the young men of to-day which will not brook anything but a progressive spirit among its educational leaders. Certainly the veterinary profession has demonstrated that there are among its leaders men who are progressive, able and mellowed by a culture which extends beyond their own science and art. They have proved themselves to be wise administrators as well as first-class practitioners of their profession. They are, like the medical men, determined to uphold their just rights, but they are not willing to do this obstinately or to refuse that patient but firm conciliation which has always been the mark of the ablest men throughout the centuries. They are aware, like the leaders of the medical and other professions, that conciliation, reasonableness and wise judgment are required of all responsible men at a time when the whole world is being reconstructed on a basis of good-will and the best possible service by all for the greatest good of the whole. It is not to be expected that the authorities of British universities will be any less conscious of their national responsibilities, nor any less willing to reach a speedy and just solution of the relatively minor difficulties presented by the recommendations of this report.

# THE SUPREMACY OF REASON

## '42 to '44

A Contemporary Memoir upon Human Behaviour during the Crisis of the World Revolution. By H. G. Wells. Pp. 212. (London: Martin Secker and Warburg, Ltd., 1944.) 42*s*. net.

MR. WELLS is indefatigable, and advancing years seem in no way to diminish the output or readiness of his pen. This "Contemporary Memoir" consists of two parts with three appendixes, the sequence and relation of which are by no means so apparent as they might be. Even the sedulity which Mr. Wells demands of his reader at the point of his preface might well fail to reveal a common theme or dominant *motif*. Moreover, only part of the book is new—how much even one with the full range of Mr. Wells's more recent writings in front of him might not be able to say with any certainty—and the high price will scarcely dispose a reader to excuse the compilation of so much material from previous writings without at least some biographical reference. Evasiveness or indefiniteness on this point is not confined to his own writings, for in this matter Mr. Wells is thoroughly inconsistent. Sometimes he provides a complete reference to a book that has interested him, but he quotes several pages from what is presumably General Smuts's address to the South African Institute of Race Relations in January 1942 without bothering to insert the line that would help a reader who wished to confirm his quotation or consult the full text to trace the New Africa Pamphlet No. 2, "The Basis of Trusteeship", in which that speech has been printed.

What might be overlooked in the journalist can scarcely be condoned in a more serious study that claims to be an autobiography of ideas, in some ways continuing, supplementing and expanding Mr. Wells's earlier "Experiment in Autobiography". Moreover, as giving the mature views of Mr. Wells as philosopher summing up his position after a life-time of work and study, the book might be placed in the philosophical class. That claim may indeed be contested, for if Mr. Wells is a true philosopher, can his irrepressible vitality and imagination ever allow him to be mature ? There are serious passages in the book and flashes of the brilliant and imaginative writing we expect from him. For the most part, it is journalism —inconsistent, sometimes irrelevant, even dogmatic or bullying, but always Mr. Wells, as when the kindly *aria* in praise of Beatrice Webb breaks the thundering notes of the grand *oratorio* of the private —or is it the public ?—hates of Mr. Wells which occupy so much of the second part of the book. Mr. Wells tries hard at times; but his comments are seldom as detached as they purport to be. They are usually lively, often intemperate—as he readily admits—and sometimes stimulating and suggestive, which after all is one reason why this author is read.

In the first part of the book, Mr. Wells discusses the reasons for the recrudescence of cruelty in this modern world, and ends on the optimistic note that the idea of a new world based on a universally valid declaration of equal human rights is now making headway against every device of its antagonists. In this part Mr. Wells is happily irrelevant, and in view of the warning to the reader in his preface, one may well wonder whether he has not started off by deliberately making his argument obscure, or whether in some Puckish mood Mr. Wells has not written

the whole book as a test for reader or reviewer to see what they would make of it. Certainly this first part completely falsifies the claim on the wrapper that it is detached from immediate contemporary political and social developments. Did Mr. Wells make that claim himself with his tongue in his cheek, or does he also need deliverance from the writer of 'blurbs' ?

The idea of a declaration of the universal rights of man is the most substantial feature of the second part of the book. Entitled "How We Face the Future", and promising to study the drama of John Ball and Richard II in modern dress, its exposition of the idea of the universal rights of man proves but the overture to the oratorio of hate. Beginning with the Communist Party the tempo quickens and the stops are pulled out as Mr. Wells indulges in his dislikes of the War Office, Mr. Alexander, President Roosevelt, General de Gaulle, Sir Samuel Hoare and Lord Vansittart, culminating with Sir Richard Acland and the Roman Catholic Church as a grand finale.

There is nothing scientific in all this, but the objects of Mr. Wells's dislikes appear to him to have a common feature in being obstacles to the penetration of a scientific spirit and outlook into public affairs. It is obscurantism and prejudice, whether professional, political or religious, that arouse his wrath. His tirade against the Admiralty in the section "Invention and Professionalism apropos the U-boat War" is inspired by the Admiralty's apparent reluctance to examine thoroughly an idea for the use of the helicopter; but Mr. Wells prejudices what appears to be a *prima facie* case for searching official inquiry by his loose reference to "hundreds" of battleships.

The three appendixes to the book are, first, a thesis accepted by the University of London for the doctorate of science "On the Quality of Illusion in the Continuity of the Individual Life in the Higher Metazoa, with Particular Reference to the Species *Homo sapiens*" ; second, a memorandum on the relation of mathematics, music, moral and æsthetic values, chess and similar intellectual elaborations to the reality underlying phenomena ; and, third, a memorandum on survival. The last is a reiteration of Mr. Wells's conviction, so long and consistently and sincerely expounded, that the survival of man and of civilization depend upon our overcoming the stupid and uncritical resistance to thought and inquiry. Knowledge or extinction, he maintains, is the only choice for man. He has no use or place for the emotions or for tradition : reason and the intellect must be the sole controlling factors. Exactly how science alone is to reorganize human affairs for a new and happier adaptation of our interests and emotions to the state of affairs which the brighter factors of our life have brought about is not clear.

Mr. Wells, though intensely individualistic himself, and with the faculty for looking at things at unusual angles, does not believe in individualism, and the main theme of his present thesis is that the integrality of the individual is a biologically convenient delusion. Personality is an illusion ; yet, he argues, it is compatible with an impersonal overriding intelligence. But how in default of leadership and personality a new and broader education system throughout the world is to issue in a federated political and economic order and a common fundamental law of human rights, in which a great impersonal society with an unprecedented range of variability is to develop, is never explained. The nearest approach to an explanation is the comment, in a chapter on "The Propaganda of World Unity", that such bodies as the Combined Raw Materials Board, the Production and Reserves Board, the Food Board, the Middle East Supply Centre, which we have already been obliged to set up for war purposes, must be developed for the establishment of world order when hostilities cease, and that from them world control of the new order must spring. Beneath the shelter of these world-wide settlement commissions and their over-riding powers, and so long as the universal rights of man are respected, national governments, great and small, can continue to develop the idiosyncrasies of their various nations and peoples, freely and securely.

Mr. Wells's chief hope is this functional line of advance, and his undying confidence in the supremacy of reason is as conspicuous as the sincerity of his passion for reform.

This is not one of Mr. Wells's great books, and no one should read it as an introduction to his work. But in a book that insists so strongly on the illusion of personality, it is Mr. Wells's own personality that is dominant, sincere and forceful. If his cosmic imagination is only evident here and there, and his philosophy uncertain, there is enough of the real Wells in this testament of impatience to redeem its shortcomings for those who measure it against earlier and finer books which have set the standard of judgment. R. BRIGHTMAN.

## FOURIER SERIES

Fourier Series

By G. H. Hardy and W. W. Rogosinski. (Cambridge Tracts in Mathematics and Mathematical Physics, No. 38.) Pp. viii+100. (Cambridge: At the University Press, 1944.) 8*s.* 6*d.* net.

THIS important new Cambridge tract is concerned with the modern developments of the *mathematical* theory of Fourier series. The character of this theory was radically altered during the decade 1900–10 by three fundamental discoveries : (1) the Lebesgue integral (1902–6) ; (2) the Fejér theorem (1904) ; (3) the Riesz-Fischer theorem (1907).

For any function $f(x)$ defined uniquely in the interval $(-\pi, \pi)$ to possess a Fourier series, it is sufficient that

$$\int_{-\pi}^{\pi} f(x)\, e^{inx}\, dx$$

should exist for all integers $n$ including zero.

Lebesgue's definition of the integral, considerably more comprehensive than those which had preceded it, brought an immediate extension to the class of functions possessing Fourier series, and it has by now almost entirely superseded the older integrals in the mathematical treatment of this and allied subjects.

The classical ideas of convergence had been investigated thoroughly in regard to Fourier series by Dirichlet and others, and had shown themselves to be insufficiently powerful to deal satisfactorily with the problems that had arisen. In this connexion, Fejér (using Cesàro's process of summation by arithmetic means) succeeded in establishing the fundamental result that any function which is continuous or possesses simple discontinuities gives rise to a Fourier series which is (uniformly) summable $C,1$ to the 'correct' sum.

The combination of these two new ideas produced the now famous Fejér-Lebesgue theorem, which shows, in modern language, that summability $C,1$ is a 'Fourier-effective' process; that is to say, it sums the Fourier series to the 'correct' sum almost everywhere. This, it is worthy of note, is in marked contrast to classical convergence; in fact, Kolmogoroff has recently demonstrated the existence of Fourier series which are *nowhere* convergent.

F. Riesz and E. Fischer, working independently, were finally able to formulate a precise converse of the old formal result known as Parseval's theorem (1799). The existence theorem bearing their name is to the effect that, if $\sum_{n=1}^{\infty}(a_n^2+b_n^2)<\infty$, there exists a measurable function, with an integrable square modulus (that is, a function of the Lebesgue class $L^2$) with these numbers as Fourier constants, and furthermore that the partial sums of the Fourier series converge *in mean* to this function. With reference to this it should be observed that the Lebesgue integral plays an indispensable part in the proof; in fact, the theorem is *false* for any definition of the integral narrower than that of Lebesgue.

With these fundamental ideas in view, the reader will find in this tract an admirably lucid and precise account of most of the major developments which have taken place during the last forty years. The authors have used the Lebesgue definition of the integral throughout, at the same time indicating those theorems which remain true, *mutatis mutandis*, if Riemann or Cauchy integrals be used. To say that a given trigonometrical series is a Fourier series is to say that a certain set of integral equations has a solution, and the meaning of such a statement plainly depends on the type of integral used. A definition wider than that of Lebesgue, for example, would in general increase the class of functions possessing Fourier series, just as a narrower one would decrease it.

After a preliminary chapter consisting principally of introductory concepts, there follows a discussion on orthogonal systems of functions of $L^2$. Any theorem proved for a series of such functions is true *a fortiori* for an *ordinary* Fourier series in virtue of the orthogonality of the sequence $\{e^{inx}\}$, and this affords an interesting (and indeed valuable) logical approach to the theory. In most cases such theorems on Fourier series are admittedly deducible by independent (though not necessarily more elementary) methods and, where possible, the authors have provided alternative proofs.

The standard tests for convergence, those of Dini, Jordan, de la Vallée Poussin and Lebesgue, and their relation one to another, are then dealt with, and their analogues for the conjugate series (not necessarily itself a Fourier series) are also provided.

Following Toeplitz, the authors then investigate the application of generalized summation processes to trigonometrical series; in particular the Cesàro and Abel methods, both possessing positive kernels, are shown to be Fourier-effective.

Finally, a chapter dealing with 'uniqueness' theorems is supplied, culminating with the result of de la Vallée Poussin that if a trigonometrical series converges, except possibly in an enumerable set, to a finite integrable function, then it is necessarily the Fourier series of that function.

The entire tract is a model of clarity and precision, the authors having spared no pains to ensure that the reader shall never be at a loss to follow them, even through their most intricate arguments. It is true that there are one or two paragraphs (for example, in the proof of Gergen's modified form of Lebesgue's convergence test, and again in the construction of a Fourier series which diverges almost everywhere) where the logic is convincing, but where a little explanation of the reasons underlying the mode of building up the argument would aid comprehension; but for this omission we must doubtless blame the severe compression, without which it would have been impossible to display such a wealth of valuable material within the short space of a hundred pages.

This tract cannot fail to be of inestimable value, particularly as a 'curtain raiser' to Zygmund's standard treatise.

## AUSTRALIAN ORCHIDS

### The Orchids of New South Wales

By the Rev. H. M. R. Rupp. Pp. xv+152. (Sydney: National Herbarium, Botanic Gardens, 1943.) 9s. net.

When the first handbook of the New South Wales flora was published in 1893 it contained descriptions of one hundred and seventy-three orchids, whereas in the work under review the Rev. H. M. R. Rupp provides descriptions of no less than two hundred and forty-eight. The large majority of these orchids are terrestrial species, only fifty-two being epiphytes, and they include a number of interesting genera, among which may be cited Prasmophyllum and Cryptostylis. Of the former, rather more than half the eighty known species are dealt with here, while of the latter twenty species are known and three occur in New South Wales. In all the members of these two genera the inferior ovary, instead of exhibiting the half-twist through 180°, as in most orchids, undergoes a complete twist during development so that the flower has a normal orientation but is reversed compared with most orchid flowers. One naturally thinks of the analogy with the leaves of Alstroemeria, where most species exhibit a twist of the base that brings about complete reversal, while in a few an edge-on position of the leaf is assumed as the leaf-base only undergoes a half-turn. The changes, both anatomical and morphological, which accompany such complete reversal, may be profound, and the fact that these ensue, rather than, what would appear simpler, namely, complete suppression of twisting, suggests a sort of momentum in evolution, since further genetical changes in the same direction appear to be more readily achieved than such as would be accompanied by a reversion to the ancestral condition.

The text of this work furnishes keys to the genera and species, and descriptions of the latter, accompanied by an account of their distributions. The twenty-three full-page figures illustrate the habit and floral structure of some of the more important types. The first descriptions of more than thirty of the species of this region we owe to the author, which gives some indication of the extent to which this aspect of systematic botany in New South Wales is indebted to his studies.

The Rev. H. M. R. Rupp belongs to that honoured band of gifted amateurs who have devoted their leisure to taxonomic studies, and the present volume is a valuable contribution to the new Flora of New South Wales to which the author looks forward.

E. J. SALISBURY.

# WILLIAM GILBERT AND THE SCIENCE OF HIS TIME*

By PROF. SYDNEY CHAPMAN, F.R.S.
Imperial College of Science and Technology

THIS four hundredth anniversary of William Gilbert's birth† offers an occasion for a brief review of his influence on the science of his time (apart from medicine), and of his researches and book on magnetism and electricity, the firm base of his enduring fame.

These researches, extending over about eighteen years**, might seem ample to occupy the leisure of so eminent and active a physician. But the Elizabethan physicians were notably versatile, as Bacon thus remarked:

"For in all times, in the opinion of the multitude, witches and old women and impostors have had a competition with physicians. And what followeth? Even this, that physicians say to themselves, as Solomon expresseth it upon an higher occasion, 'If it befall to me as befalleth to the fools, which should I labour to be more wise?' And therefore I cannot much blame physicians, that they use commonly to intend some other art or practice, which they fancy, more than their profession. For you shall have of them antiquaries, poets, humanists, statesmen, merchants, divines, and in every of these better seen than in their profession." ("On the Advancement of Learning", Book II, Section X, 2, 1605.)

Gilbert shared this versatility to an exceptional degree, while yet adorning his profession. In his early days he had given much time to experiments on chemistry, "attaining to great exactness therein"††: this indeed was a natural extension of his work as a physician. He was also an ardent student of astronomy, and the first Englishman to accept and propagate the revolutionary views of Copernicus (1473–1543) and Bruno (1547–1600) on the motions and the nature of the celestial universe.

Medicine, chemistry, astronomy, magnetism and electricity—indeed, his range of studies was wide; and although these sciences (except astronomy) were still in their rudiments, their literature was already great. The invention of printing by movable type, in 1453, had led by Gilbert's time to the appearance of printed copies of the principal ancient authors. Already booksellers had set up their trade in London. Gilbert was doubtless a good customer, eagerly buying and reading the classical, medieval and modern books as they appeared. Most of them, like Gilbert's own book, "de Magnete", were in Latin, either original or translated, thus obviating, for the learned men of that time, the curse of Babel, and making Europe a republic of learning.

To illustrate the wealth of Gilbert's learning, let us note a selection from the authors quoted in "de Magnete":

Among the Greeks, they include the fathers of medicine, Hippocrates (*c.* 430 B.C.)* and Galen (A.D. 131–201); the philosophers Empedocles (*c.* 500–430 B.C.), Plato (427–347 B.C.) and Epicurus (342–270 B.C.); the historian Plutarch (*c.* A.D. 45–120); the astronomers Thales (*c.* 624–565 B.C.), Aristarchus (*c.* 310–230 B.C.), Hipparchus (*c.* 190–120 B.C.) and Ptolemy (*c.* A.D. 170); the mathematicians and scientists Pythagoras (born *c.* 582 B.C.), Anaxagoras (488–428 B.C.), Aristotle (384–322 B.C.) and Hero (*c.* A.D. 100)†. Among the ancient writers of Latin, he quoted Lucretius (*c.* 95–55 B.C.), Pliny (A.D. 23–79), Tacitus (A.D. 55–120) and St. Augustine (A.D. 354–430).

His medieval references include Geber the Syrian (*c.* 850), Rhazes the Persian (865–925), Avicenna of Bokhara (980–1037) and others who wrote in Arabic; Albertus Magnus (1206–1280), Roger Bacon (1214–1294), Thomas Aquinas (1227–1274) and Petrus Peregrinus (whose famous "Epistola" was written in 1269).

Among the moderns, as reckoned in Gilbert's time, he quoted Cardinal Cusa (1401–64), Copernicus (1473–1543), Fracastor (1483–1543), Paracelsus (1493–1541), Agricola (1490–1555), Cardan (1501–76), Fallopius (1513–62), Oviedus (who wrote a "History of the East Indies", 1525), Stevinus (1548–1600), Tycho Brahe** (1546–1601), and three contemporaries, Robert Norman, William Borough and William Barlowe, who wrote on magnetism in English.

These authors were philosophers, physicians, theologians, mathematicians, astronomers, biologists, metallurgists, navigators and historians. Some were quoted only in the astronomical chapter with which "de Magnete" concludes, but most of them had something to say about magnetism. This is not surprising, because in the magnet Nature affords her simplest example of a field of force of notable intensity surrounding objects that are of moderate size, fairly available and widespread, and easy to handle. This was bound to attract notice and comment by writers of all kinds, and to be used by theologians, philosophers and poets as a basis for theories and analogies, by the early physicians as an ingredient of strange potions, and by magicians as a tool to impress the ignorant, as well as by navigators and landsmen in the form of the compass.

Many of those who wrote of the magnet did so only by hearsay, and to the wonderful truth was added a fantastic growth of fable and error, such as that the loadstone's magnetic power was dulled at night; that when weak it is revived if bathed in goat's blood; that it has the power to reconcile husbands to wives, and brides to husbands; and that if pickled in the salt of a sucking fish it gains the power to pick up gold from the deepest wells.

In writing "de Magnete", the first substantial modern scientific treatise, giving a systematic account of magnetism, Gilbert wished to clear away the current errors as well as to establish the truth. He found, in fact, far more to condemn than to retain in his predecessors' writings on magnetism, and he did not scruple to castigate the errors and false theories even of the greatest among them. For example, he says that to the one sole magnetic property, attraction, known to the ancients††, "were added certain fragments and falsehoods: which in the earliest times, no less than nowadays, used to

* Address delivered at a commemorative meeting held by the Royal Society of Medicine on April 5.

† According to the reckoning (which is not certain) of the late Prof. Silvanus Thompson.

** See p. xi of de Mottelay's introduction to his (the first) English translation of "de Magnete". The basis for the mention of eighteen years is presumably Edward Wright's statement, in his 'encomiastic preface' to "de Magnete", that the magnetic philosophy had been "kept back not till the ninth year only (as Horace prescribes) but already unto almost a second nine".

†† Quotation given by de Mottelay, in his introduction, p. xxv; the source is not stated.

* Most of the dates here given are taken from Singer's "A Short History of Science" (Oxford, 1941).

† Though neither Euclid (*c.* 330–260 B.C.) nor Archimedes (287–212 B.C.) were mentioned.

** But Gilbert's other famous astronomical contemporaries Galileo (1564–1642) and Kepler (1571–1630) are *not* mentioned.

†† In this and later quotations from "de Magnete", I follow (almost completely) the English translation published in 1900 for the Gilbert Club, and printed (250 copies only) by the Chiswick Press.

be put forth by raw smatterers and copyists to be swallowed of men. As for instance, that if a loadstone be anointed with garlic, or if a diamond be near, it does not attract iron. Tales of this sort occur in Pliny, and in Ptolemy's *Quadripartitum*; and the errors have been sedulously propagated, and have gained ground (like ill weeds that grow apace) coming down even to our own day, through the writings of a host of men, who, to fill out their volumes to a proper bulk, write and copy out pages upon pages on this, that and the other subject, of which they knew almost nothing of their own experience. Such fables of the loadstone even Georgius Agricola himself, most distinguished in letters, relying on the writings of others, has embodied as actual history in his book *De Natura Fossilium*". ("de Magnete", Book I, Chapter 1.)

"Almost nothing of their own experience," Gilbert here says, and it is the kernel of his criticism. The importance of experiment is expressed with equal clarity and firmness in his comments on the writings of those whom he revered, as in this passage:

"Thomas Aquinas, writing briefly on the loadstone in Chapter VII of his *Physica*, touches not amiss on its nature, and with his divine and clear intellect would have published much more, had he been conversant with magnetic experiments". (Book I, Chapter 1.)

Experiment, where experiment is possible, is the keynote of Gilbert's philosophy; thus, as he says in his preface:

"we have proposed to begin with the common magnetic, stony and iron material, and with magnetical bodies, and with the nearer parts of the earth which we can reach with our hands and perceive with our senses; then to proceed with demonstrable magnetic experiments. . . . For after we had . . . seen and thoroughly examined many of those things which have been obtained from mountain heights or ocean depths, or from the profoundest caverns and from hidden mines: we applied much prolonged labour on investigating the magnetical forces: . . . Nor have we found this our labour idle or unfruitful; since, daily during our experimenting, new and unexpected properties came to light".

This method is now a commonplace of science, but in Gilbert's time ancient authority was the basis of truth for all but a challenging few, like Gilbert and Galileo. Hence Gilbert had no bright anticipations of the reception his book was likely to gain. Why should I, says he:

"expose this noble philosophy, which seems new and incredible by reason of so many things hitherto unrevealed, to be damned and torn to pieces by the malediction of those who are either already sworn to the opinions of other men, or are foolish corrupters of good arts, learned idiots, grammatists, sophists, wranglers, and perverse petty folk". (Preface.)

His appeal was therefore, avowedly, to the few:

"But to you alone, true philosophizers, honest men, who seek knowledge not from books only but from things themselves, have I addressed these magnetical principles in this new sort of philosophizing. But if any see not fit to assent to these self-same opinions and paradoxes, let them nevertheless mark the great array of experiments and discoveries (by which notably every philosophy flourisheth), which have been wrought out and demonstrated by us with many pains and vigils and expenses. In these rejoice, and employ them to better uses if you can". (Preface.)

The need for a much more active and extensive use of the experimental method was urged by Francis Bacon, in his "Advancement of Learning" and other books, published after Gilbert's death, but probably influenced by Gilbert's example. Thus, writing from the point of view of a man of affairs, regarding the steps that needed to be taken to advance learning, after noting that books, maps, globes, astrolabes, botanic gardens, and dead bodies for anatomy were among the needs for which there was already some provision, Bacon says:

"there will hardly be any main proficience in the disclosing of nature, except there be some allowance for expenses about experiments; whether they be experiments appertaining to Vulcanus or Daedalus, furnace or engine, or any other kind. And therefore as secretaries and spials of princes and states bring in bills for intelligence, so you must allow the spials and intelligencers of nature to bring in their bills; or else you shall be ill advertised.

"And if Alexander made such a liberal assignation to Aristotle of treasure for the allowance of hunters, fowlers, fishers and the like, that he might compile an history of nature, much better do they deserve it that travail in arts of nature". ("Advancement", **2**, 10, 11.)

Gilbert, however, paid his own expenses for experiment, and was content to go his own way, in advance of his time. His independence of mind was shown in "de Magnete" and also in other ways. The title page gives *first* his own name, before that of the book. Then comes a preface to the "candid reader", written, as my quotations will have shown, in a proud confident tone. Contrary to the custom then and for two centuries more, he made no dedication to a patron. In this, as in his experimenting, he practised what Bacon afterwards preached but did not practice; for Bacon, in the "Advancement of Learning", addressed, rather fulsomely, to James I, wrote:

"Neither is the modern dedication of books and writings, as to patrons, to be commended: for that books (such as are worthy the name of books) ought to have no patrons but truth and reason. And the ancient custom was to dedicate them only to private and equal friends, or to entitle the books with their names: or if to kings and great persons, it was to some such as the argument of the book was fit and proper for: but these and the like courses may deserve rather reprehension than defence". (Book I, Sect. III, 9.)

Gilbert, indeed, almost reversed the custom of dedication, by publishing, next after* his own preface to the candid reader, an encomiastic preface "To the most eminent and learned man Dr. William Gilbert, a distinguished Doctor of Medicine amongst the Londoners, and Father of Magnetic Philosophy". This was written by Edward Wright (1558 ?–1615), a noted Elizabethan mathematician and teacher of astronomy and navigation.

As a scientific author Gilbert showed many virtues. Though "de Magnete" had no index of subjects or authors, Gilbert included an ample index of chapters (without page numbers). The treatise is divided into six books, comprising 115 chapters, so that the list of chapter titles gives a clear and full indication of

* In de Mottelay's English translation of "de Magnete", the order of the two prefaces is reversed; no reason for this erroneous order is given.

the contents and structure of the book. It is a substantial work containing about 120,000 words, and is well illustrated with ninety woodcuts (not numbered) of diagrams and pictures of loadstones and apparatus. It also contains a glossary of eighteen new scientific terms that Gilbert found it convenient to introduce. The book contains no footnotes, but an interesting innovation was the use of marginal stars, of two sizes, to indicate the discoveries and experiments described, "according to the importance and subtlety of the matter" (Preface); there were twenty-one large stars and two hundred small ones; most though not all of these starred experiments and discoveries were originated by him. This notably individual feature of the book is of great interest as showing Gilbert's estimation of the relative value of his experiments.

## Experimental Work on Magnetism

Gilbert's "de Magnete" made three great contributions to science; the first was the ordering and extension of magnetic knowledge, on the basis of experiments originated or verified by himself. The second was the ordering and extension of electric knowledge, in the same way. The third, and in my opinion the greatest, was his conception of the earth itself as a great magnet.

Gilbert had a great predecessor among writers on magnetism, Petrus Peregrinus, who in 1269 wrote a famous letter to a friend, of which many manuscript copies were made, until it was printed in 1558. In this letter Petrus clearly stated that the loadstone has two unlike poles, and showed how to find and recognize them by means of small auxiliary needles laid on the loadstone. Petrus had a fancy to shape his loadstones spherical, like the earth and the celestial bodies, and to mark on them lines of magnetic direction like meridians joining the two poles. At either pole a small needle will stand perpendicular. One pole seeks the north, and the other the south. Like poles repel, unlike poles attract each other. Iron can be magnetized by the touch or stroke of the loadstone, thus acquiring the loadstone's attractive, repulsive and directive properties. When a loadstone is cut in two, a pair of opposite new poles appears, one on each part, so that each becomes a complete magnet, with two opposite poles.

This letter by Petrus, firmly based on experiment, is a magnificent scientific classic, despite some fallacies of perpetual motion in its second part, of which the author himself seemed doubtful.

Petrus wrongly thought that the magnetic compass pointed to the *true* north. He ascribed this to celestial influences exerted from the whole heavens, not only from the celestial poles; he did not attribute it, as many others did, to the 'nautical' or pole star, for he knew that this was not at the true celestial pole.

After his time, it became known that the magnetic compass does not point to the true north, and gradually knowledge was accumulated about the distribution of this magnetic declination, which varies from place to place. The first discoverers of the magnetic declination are not known.

Then in 1581, Robert Norman, a maker of compasses at Limehouse, discovered the magnetic dip of a magnetized needle perfectly balanced before magnetization. He examined and studied this discovery with great ability; in particular, he concluded from it that the earth, not the sky, controls the direction of the magnet, and he showed that the earth did not *attract* the magnet but only *turned* or directed it.

These were the foundations on which Gilbert built. He mentions Petrus and Norman several times, though more often to condemn their few errors than to praise their great merits. He refers to "a little work, fairly learned for the time, going under the name of one Petrus Peregrinus, which some consider to have originated from the views of Roger Bacon, the Englishman of Oxford" (p. 5): Norman he described as "a skilful seaman and ingenious artificer, who first discovered the dip of the magnetic needle" (p. 8).

Of Gilbert's twenty-one big-star experiments, two were electric and nineteen magnetic; of the two hundred with small stars, twenty-nine were electric and a hundred and seventy-one magnetic.

My time permits only brief mention of even the big-star experiments. Gilbert experimented with loadstones and magnets of many shapes, but like Petrus he specially favoured the spherical form, which he called a terrella. On this, again like Petrus, he marked the lines of magnetic direction from pole to pole; these he named "magnetic meridians". He also marked the "magnetic equator" midway between the poles, and intermediate circles of "magnetic latitude", such as the arctic and tropical. Whereas Petrus he had merely *laid* little magnetic needles on his round loadstone, Gilbert *pivoted* his, each on a little stand, and showed that between the equator, where they lie parallel to the surface, and the poles, where they stand perpendicular, the needles rest inclined. In this he saw a parallel to the magnetic dip on the earth, discovered by Norman; with bold imagination, overstepping an enormous disparity of size, he leapt to the conclusion that the compass needle turns northward, and dips, because to the earth it is what his pivoted needles were to the terrella, and hence that the earth itself is simply a great spherical magnet. To quote his own words (in translation): "The magnetic dip (which is the wonderful turning of magnetic things to the body of the terrella) in systematic course, is seen in clearer light to be the same thing upon the earth. And that single experiment, by a wonderful indication, as with a finger, proclaims the grand magnetic nature of the earth to be innate and diffused through all her inward parts". (Book VI, Chapter 1.) This conclusion, which is the foundation of the science of geomagnetism, has never been seriously contested, though we still do not know *why* the earth is magnetic.

Gilbert's further developments of geomagnetism were not so successful. He ascribed the compass declination, or departure from the true meridian, to the inequalities of the earth's solid surface on land or under the sea, and he concluded that near either coast of a great ocean the needle should turn somewhat landwards. This was disproved nearly a century later by Halley (1656–1742). Further, Gilbert concluded that without cataclysmic changes, such as the submergence of the fabled continent of Atlantis, the magnetic declination at each place must remain for ever constant; this was disproved in 1635 by Gellibrand, a Gresham professor, from fifty years of compass observations in London.

Gilbert, though a great reader and a devoted experimenter, was no recluse. His friends included not only physicians, astronomers and mathematicians, but also sailors, to whom there are many references in "de Magnete"; for example, in Book III, Chapter 1, on the compass direction, he writes that certain facts "have been pointed out to me and confirmed by our most illustrious sea-god, Francis Drake, and by

another circumnavigator of the globe, Thomas Candish". Gilbert hoped that his experiments and discoveries would add to the already great usefulness of the magnetic needle to mariners. The Dutch scientist Stevinus had pointed out that when the distribution of the magnetic *declination* had been well observed in many parts of the earth, it should conversely be a help to mariners (knowing their latitude) in determining their *longitude*; Gilbert shared this hope, though he knew that the distribution was not simple, and he added the new proposal that the magnetic *dip* would enable mariners to find their *latitude* when astronomical observation was impossible. But both these ideas proved fruitless, owing to the irregular distribution of the earth's magnetism, and its constant slow change. Before this became clear, Briggs, the introducer of *common* logarithms (to the base 10), had spent much wasted labour on calculations of the magnetic dip in different latitudes, on the basis of a rather fantastic geometrical construction proposed by Gilbert, with no real foundation either in experiment or theory.

Passing from these, Gilbert's faulty additions to his most brilliant discovery, let us consider briefly his experimental work in pure magnetism and pure electricity. In these he greatly extended the range of substances known to be magnetic or electric. He also distinguished very clearly between magnetic and electric actions, and added many important details, some of them quantitative, to our knowledge of both.

He attained to the conception of what we now call the magnetic field surrounding a magnet, or, in his words, its "orb of virtue". He attained also to the conception of what we call uniform intensity of magnetization, showing that the magnetic influence of a terrella is not something emanating only from the poles, but is an aggregate effect of all its parts. He disproved the asserted anti-magnetic influence of the diamond by assembling no less than seventy excellent diamonds, in the presence of many witnesses, around loadstones and magnets, without any observable magnetic change. (Book III, Chapter 13.)

He found that the magnetization of a body can be destroyed by heating it to redness, but that heated iron, in cooling, acquires a small intensity of magnetization in the north – south direction, from the earth's magnetic field. He observed that soft iron, even without heating, becomes slightly magnetized by the earth's field, either slowly, over many years, or more rapidly if it is hammered while lying north and south. He showed also that a sheet of iron can partly screen the space on one side of it from the magnetic field or action of a loadstone on the other side.

He showed that a magnet could support a much greater weight of iron if soft iron caps were put over its poles.

He improved instruments of magnetic observation, including Norman's dip needle; and he collected data as to the compass direction* in different regions.

## Work on Electricity

Gilbert's work on electricity is given, almost as a digression, in one chapter (Book II, Chapter 2), entitled "On the Attraction of Amber, or more truly, on the Attaching of Bodies to Amber"; this chapter also describes various experiments on what we now know as surface tension. Silvanus Thompson, who was an enthusiastic reviver of Gilbert's memory, summed up his experimental discoveries in electricity as follows:

(1) The generalization of the class of *Electrics*. (2) The observation that damp weather hinders electrification. (3) The generalization that electrified bodies attract everything, including even metals, water and oil. (4) The invention of the non-magnetic versorium or electroscope. (5) The observation that merely warming amber does not electrify it. (6) The recognition of a definite class of non-electrics. (7) The observation that certain electrics do not attract if roasted or burnt. (8) That certain electrics when softened by heat lose their power. (9) That the electric effluvia are stopped by the interposition of a sheet of paper or a piece of linen, or by moist air blown from the mouth. (10) That glowing bodies, such as a live coal, brought near excited amber discharge its power. (11) That the heat of the sun, even when concentrated by a burning mirror, confers no vigour on the amber, but dissipates the effluvia. (12) That sulphur and shell-lac when aflame are not electric. (13) That polish is not essential for an electric. (14) That the electric attracts bodies themselves, not the intervening air. (15) That flame is not attracted. (16) That flame destroys the electrical effluvia. (17) That during south winds and in damp weather, glass and crystal, which collect moisture on their surface, are electrically more interfered with than amber, jet and sulphur, which do not so easily take up moisture on their surfaces. (18) That pure oil does not hinder production of electrification or exercise of attraction. (19) That smoke is electrically attracted, unless too rare. (20) That the attraction by an electric is in a straight line toward it.

Few substantial advances on Gilbert's work in pure magnetism and electricity were made for more than a century. The quantitative laws of magnetic action, sought by Halley in 1687 and later without much success, were first established by Coulomb (1736–1806) by means of his torsion balance (1785). The first notable advance beyond Gilbert in electrical knowledge was made by Otto von Guericke (1602–86), burgomaster of Magdeburg, the inventor of the air pump; he constructed the first electrical machine, namely, a globe of sulphur, which when rotated, while a hand was pressed upon it, became electrically charged. He also showed that there are two kinds of electricity, and that bodies charged with the same kind repel one another, whereas Gilbert knew only of electric *attraction*.

## Astronomy

The last Book (VI) of "de Magnete" is mainly astronomical, and is of great interest for its long serious argument in favour of the Aristarchean and Copernican hypothesis that the earth rotates, rather than that the sun, moon, planets and stars all revolve daily round the earth. Gilbert supplied an additional argument of his own, finding in the geomagnetic axis a real terrestrial feature with which the daily rotation is associated, whereas in the common view the axis of rotation was not terrestrial but celestial. He asserted that the magnetic axis remains invariable in the earth, but that, with the earth, it turns round the pole of the ecliptic, thus causing the precession of the equinoxes. He makes only brief mention of the earth's orbital motion (see "de Magnete", p. 232, Gilbert Club edition, 1900). He seems to attribute the daily and precessional motions partly to the earth's magnetism. Since his day it has become clear

* S. P. Thompson, in "Gilbert of Colchester" (*J. Inst. Elec. Eng.*, 1903), states that Gilbert also collected observations of dip, but I know of no authority for this statement. "de Magnete" appears to contain not one numerical value of the dip, not even quoting Norman's observation of it, in London.

that the geomagnetic axis does not coincide with the earth's axis of rotation, and is not quite constant; we incline nowadays to attribute the earth's magnetism partly to its rotation, rather than vice versa. Newton later showed that the precessional motion of the earth's axis is due to gravitational and dynamic causes, independent of geomagnetism.

Despite his advanced philosophic outlook, Gilbert was not free from the then prevailing belief that the stars influence mundane affairs (Book VI, Chapter 8). He believed that just as "Nature has taken care, through the earth's soul or magnetic vigour", to incline its axis to the pole of the ecliptic, so that the orbital motion produces the succession of the seasons, so also "the stars shift their rays of light at the surface of the earth through this wonderful magnetical inflection" (or precession) of the earth's axis. "Hence", he said, "come new varieties of the seasons of the year, and lands become more fruitful or more barren; hence the characters and manners of nations are changed; kingdoms and laws are altered, in accordance with the virtues of the fixed stars as they culminate, and the strength thence received or lost in accordance with the singular and specific nature of each. . . ."

Gilbert's interest in astronomy was shown by his authorship of a second considerable treatise, left in manuscript at his death, and not published until by the care of a brother it was printed in Amsterdam in 1651. Its title, translated from the Latin original, was "On our Sublunary World, a New Philosophy". Though it contains several references to "de Magnete", it made no further contributions to magnetism. It expounded the then revolutionary astronomical views of Bruno, whom it cites, and is largely an anti-Aristotelian discussion on astronomy, meteorology and the tides.

Gilbert did not live long enough after the appearance of his masterpiece, "de Magnete", to learn fully whether its reception was better than he had pictured in his preface. On the whole it was well received, though the astronomical part was disclaimed by some who accepted the magnetic discoveries; among these were Gilbert's friend Barlowe, and also the Jesuits, by whom the last Book (VI) was regarded as heretical. But greater men, including Gilbert's younger contemporaries Kepler and Galileo, wrote of "de Magnete" with high praise. This judgment has been endorsed by posterity, and as the centuries have rolled on, the fame of Gilbert has stood firm, as a great pioneer of magnetic and electric experiment, and as the father of the sciences of geomagnetism and electricity.

# WILLIAM GILBERT: HIS PLACE IN THE MEDICAL WORLD*

By SIR WALTER LANGDON-BROWN

FULLER'S "Worthies" has a charming account of William Gilbert. He did not know him personally, for Gilbert had been dead five years when Fuller was born. But he had talked to people who had known him. This prompted him to write as follows: "William Gilbert was born in Trinity Passage in Colchester, his father being a Counsellour of great Esteem in his Profession, who first removed his family thither from Clare in Suffolk, where they had resided in a gentile Equipage some Centuries of Years. He had (saith my informer) the clearness of Venice glass without the Brittleness thereof, soon ripe and Long Lasting in his Perfections. He commenced Doctor in Physick, and was Physician to Queen Elizabeth who stamped on him many Marks of her favour, besides an Annual Pension to encourage his Studies. He addicted himself to Chemistry attaining to great exactness therein. One saith of him that he was Stoicall, but not Cynicall, which I understand; Reserv'd but not Morose, never married, purposely to be more beneficial to his Brethren. Such was his loyalty to the Queen that as if unwilling to survive, he dyed in the same year with her 1603. His stature was Tall, Complexion Cheerful, an Happiness not ordinary in so hard a Student and Retired a Person. He lyeth buried in Trinity Church in Colchester under a plain Monument. Mahomet's tomb at Mecca is said strangely to hang up, attracted by some invisible Loadstone; but the Memory of this Doctor will never fall to the ground, which his incomparable book 'de Magnete' will support to Eternity."

It is difficult to enlarge this admirable miniature without spoiling it. Also it is difficult to make use of Silvanus Thompson's excellent account of Gilbert without shameless plagiarism. This was written for the tercentenary of Gilbert's death celebrated at Colchester in 1903. Mr. Puryer White, of St. John's College, kindly lent me the copy belonging to the late Sir Robert Scott, formerly Master of the College, which is enriched with notes by the Master's hand, drawn from the College records concerning Gilbert's career. From these it is clear that he matriculated in May 1558. If the commonly accepted date for Gilbert's birth of 1540 is correct, this would make him eighteen when he entered, which would be rather old for those days. Hence, doubts have arisen, and dates ranging from 1540 to 1544 have been given; hence also, our justification for celebrating the quatercentenary of his birth in 1944. After graduation he was elected to a fellowship, his name being spelled Gylbert on the roll. Here again, we meet with a discrepancy in the record. Sir Robert Scott states that he was admitted on Sympson's foundation, but Bass Mallinger, a former learned if eccentric librarian and historian of the College, states "Fisher's statutes of 1530 had relieved all 'physic fellows' from the obligation of taking orders, but the statutes of 1545 had limited such exemptions to two, a proviso which continued in force until 1860. Notwithstanding this restriction, however, the sixteenth century saw three successive Presidents [of the Royal College of Physicians] elected from such 'physic fellows' of St. John's. These were—Richard Smith 1585; William Baronsdale 1589, and the eminent William Gilbert 1600. The last representative of this group was Dr. Henry Thompson, Consulting Physician to the Middlesex Hospital, who died in 1897." The present Master of St. John's College, Mr. E. A. Benians, tells me that the list of distinguished physicians who studied there in the sixteenth century was due to Bishop Fisher's insistence on encouraging the study of Greek in the College, which, despite Erasmus, encountered opposition elsewhere; and on Greek the revival of medicine was believed to be based from Linacre onwards.

The probable explanation of the apparent discrepancy is that Gilbert was elected in the ordinary way, but as he did not take orders, had to become 'physic fellow' or resign his fellowship within the stated time.

* Address delivered at a commemorative meeting held by the Royal Society of Medicine on April 5.

After taking his M.A., Gilbert acted as examiner in mathematics, and in 1569 became senior bursar at St. John's. In the same year, he was admitted M.D. and was senior fellow. In the next year he terminated his twelve years of residence in college and went abroad, travelling in Italy for three years. Not much is known of this, but from his writings it would appear that he drew inspiration from such medical men as Cardan, Fallopius and Frascatorio. He had a great repugnance to the teachings of Paracelsus and Albertus Magnus, and scoffed at Arnoldus de Villanova of Salerno. In 1573 he returned to England, as Silvanus Thompson says, "a pronounced hater of shams and quackery, a champion of the experimental method and an outspoken enemy of all those who merely relied on the authority of great names".

He did not return to Cambridge, but having been elected a fellow of the Royal College of Physicians, settled in London in Wingfield House on St. Peter's Hill, which ran from St. Paul's churchyard to Upper Thames Street, crossing what is now Queen Victoria Street just to the east of the College of Heralds. Thus he was close to the first College of Physicians, which had been Linacre's own house. Here he formed a learned society which met at his house, and they laid before Queen Elizabeth a scheme for the foundation of an Academy of Natural Philosophy which was to have been a real University of London. Nothing came of it, and the "Invisible College" did not arise for about half a century. Thus Gilbert stimulated experimental science in Britain before all Bacon's theoretical contributions to the subject. Bacon indeed repeatedly refers to him with respect in the "Novum Organum" and elsewhere.

His success in practice was rapid. In 1577 he was granted arms, which are now carved in relief in the North Court of St. John's College. From 1581 until 1590 he was a censor, and from 1587 until 1592, treasurer of the College of Physicians. He served a second term as treasurer from 1597 until his election to the presidential chair. In the year of the Armada he was one of four physicians to inquire into an epidemic that had broken out in the Royal Navy. Lancelot Browne, William Harvey's father-in-law, was another, while a third was Wilkinson, who preceded Harvey as physician to St. Bartholomew's Hospital. Gilbert had many professional associations with Lancelot Browne, who succeeded him as president of the College; considering this and the family tie between Browne and Harvey, it seems probable that the latter learned something of Gilbert's outlook. This may have been the source of information for Harvey's statement that Gilbert spent £5,000 on his researches—a large sum in those days.

In 1589 the College of Physicians decided to compile a Pharmacopœia, and Gilbert was on the committee for carrying this out. Its publication was, however, delayed until 1618. On this Silvanus Thompson remarks: "If it had appeared in his lifetime, he would not have sanctioned the inclusion of Emplastrum divinum of Nicholaus, consisting of powdered loadstone made up with wax, oil, litharge and various spices, for in *de Magnete* he had denounced the prescription in unsparing terms as an evil and deadly 'recommendation of an abominable imposture' ". For, as Gilbert said, "It is when whole that the loadstone draws. . . . The application of a loadstone for all sorts of headaches no more cures them (as some make out) than would an iron helmet or a steel cap." On the positive side, he was a great believer in iron as a fine powder steeped in the "sharpest vinegar" and dried, for the treatment of anæmia. He said that "it restores young girls when pallid, sickly and lacking colour, to health and beauty". He also advised iron for enlarged spleen; Hale White suggests that malaria then being very common in England, the patients improved because it benefited the accompanying anæmia. He was very sarcastic about many ridiculous claims made for remedies, saying: "Thus do the smatterers cross swords together and puzzle inquiring minds by their vain conjectures".

Dr. Charles Singer suggests that Gilbert's interest in experimental science was aroused by meeting Giordano Bruno who was in England during 1583–85, at Elizabeth's court, probably in the company of Sir Philip Sidney. But Gilbert did not become a Court physician until the year after Bruno's martyrdom, and that he did not frequent the Court much before is indicated by the dismay shown by his little group of scientific friends who met at his house on St. Peter's Hill when he was appointed physician to the Queen. They feared, and as the event proved, justifiably, that the removal to Whitehall would break up their coterie, and their researches would languish. Still, it is quite possible, considering the fashionable nature of Gilbert's practice, that he would have known Sir Philip Sidney and have met Bruno, even if not at Court. As evidence of the kind of practice he had, we find the Earl of Shrewsbury writing of him to a friend, [he is] "a sensible man; therefore seek to be acquainted with him and be very friendly of him". Then again, in January 1597, Gilbert attended Lady Cecil at Hatfield in her last illness. An unpleasant incident occurred during his visit; one of her jewels was missing and a Robert Wisson (or Weston) was charged with the theft. He was in attendance on Gilbert nominally as his servant, but it would appear he was probably Gilbert's nephew! However, all must have ended well, for we find Gilbert attending Lord Burghley on his death-bed a year later.

Gilbert retained his association with his native town of Colchester by the possession of the family residence of Tymperleys in Trinity Street after his stepmother's death in 1589. He resided there occasionally and became one of Colchester's leading citizens, though it is not known whether he practised there. He was always proud of his association with Colchester, and styled himself "Colcestiensis" on the title page of his great book.

In 1600 Richard Hakluyt published the third and last volume of his "Voyages", and in the dedication to Sir Robert Cecil he stated: "I was once minded to have added to the end of these my labours a short treatise which I have lying by in writing, touching 'The curing of hot diseases incident to travelers in long and Southerne voyages', which was written in English, no doubt of a very honest mind by one M. George Wateson. . . . But being carefull to do nothing herein rashly I showed it my worshipfull friend M. doctor Gilbert, a gentleman no lesse excellent in the chiefest secrets of the Mathematicks (as that rare Jewel lately set fourth by him in Latine doth evidently declare) than in his own profession of physicke; who assured me, after hee had perused the said treatise that it was very defective and imperfect and that if hee might have leisure, which that argument would require, he would either write something thereof more advisedly himselfe or would conferre with the whole College of the Physicians,

and set downe some order by common consent for the preservation of her Majesties subjects". But this scheme he never carried out. Mr. Benians kindly lent me a facsimile copy of this treatise edited by Dr. Singer. It is certainly "very defective and imperfect" though it contains some interesting references to treatment by liver for intestinal disorders (Did he encounter sprue, one wonders ?), to the value of fresh and not salted meat for scurvy, and most interesting of all, to his use of a strong infusion of pepper ? For it was not until less than twenty years ago that the richness of pepper in vitamin C was demonstrated.

Dr. Singer identifies the author with George Whetstone, the poet and swashbuckler who in 1578 wrote a crude play, "Promos and Cassandra", the original of Shakespeare's "Measure for Measure". From 1587 he disappeared from sight until the publication of this treatise in 1598, and it is fair to assume that it was during this interval that he went on the voyages which provided the material for his ideas on tropical and marine diseases.

On the death of Dr. James, Gilbert became, as already stated, physician to Queen Elizabeth; the patent gives his salary as £100 a year. He does not appear to have accompanied her on her many tours through the country, by which she spared her own pocket and conferred distinction on so many bedrooms. Her Court physicians seem to have been expected to give her New Year presents and we find that on the last new year she lived to see, Gilbert's gift was "one pott of Orange flowers and another of green ginger", while in return he received 13¾ oz. of gilt plate, so he did not do so badly on the exchange. He must have had some trying times with her, for in her latter days much success had brought with it many illusions; and as Ben Jonson remarked to Drummond of Hawthornden, "she never saw herself after she became old in a true glass". The temperament thus displayed led to terrible scenes in her last illness, in which Gilbert attended her. The description is well known. "She alternated between fits of rage and periods of silence and stupor. She railed at her physicians and her counsellors, refusing food, refusing physic, and refusing even to rest. Shortly before the end, she sat obstinately on her cushions outside her chamber, in spite of all the endeavours of ladies of the bed chamber to induce her to go to bed".

In the British Museum there is a long roll upon which Camden, the herald, has drawn in ink a representation of the funeral procession of the Queen. In this is a group of four men walking together, labelled Clerks of Parliament and Doctors of Physic. One of these, with pointed beard, ruff and hat, as in the engraved portrait of Gilbert by Clamp, leaves little doubt as to identity.

It has been repeatedly stated that Queen Elizabeth left Gilbert a pension and that he was the only man mentioned in her will. Silvanus Thompson points out that as she is not known to have left a will, the granting of a pension must remain in doubt.

Gilbert was appointed physician to James I, but did not live long enough to enjoy that office as he died on November 30 O.S., 1603. As Silvanus Thompson speaks of this being his sixtieth year, he evidently accepts the date of his birth as 1544. It would seem likely that he died of plague, which we know was then rife. The best account of the epidemic will be found in Thomas Dekker's book, "The Wonderful Yeare 1603, showing London lying Sicke of the Plague". "Every house," he says, "lookt like St. Bartholomew's Hospital." Many that "would have been glad of a bed in an hospitall, and dying in the open fields have been buried like dogs. . . . Never let any man ask me what became of our physitians in this massacre—they hid their synodicall heads as well as the prowdest. Galen could do no more than Sir Giles Goosecap"; and so on in the approved euphuistic mode. But Gilbert neither fled nor hid himself. Michael Hicks, who had been secretary to Queen Elizabeth, wrote to the Earl of Shrewsbury thus: "I heard as I was writing here of that Dr. Gilbert the physician is dead who was my neighbour at St. Peter's Hill. He was a learned physician and an honest. The sickness is greatly diminished in London, and the citizens do return in great numbers". The association between these two sentences points to plague as the cause of death.

Gilbert lived a bachelor and died a wealthy man. Besides money, he bequeathed to the College of Physicians his library, globes, instruments and cabinet of minerals; but all these were lost in the Great Fire of London except a few folio volumes, which cannot now be identified.

In 1904, the year after the Colchester celebration of the tercentenary of Gilbert's death, an interesting document was discovered bearing his autograph and seal. Owing to Mr. Puryer White's kindness, I can tell the whole story from the records of St. John's College. Dr. Fenn having succeeded to the ownership of Alston Court, Nayland, found therein boxes of old documents. Among them was a power of attorney executed by Gilbert in favour of Robert Middleton, his attorney. The ink in some parts had eaten its way through the paper, leaving the words like charred stencils in the thin, yet finely made paper. He communicated his discovery to his cousin, G. D. Liveing of St. John's. Apparently the house at Nayland had belonged to their great-grandfather, who had been executor to Thomas Bayles, whose forbears had succeeded to Middleton's practice at Colchester. The witness to the document was Gilbert's brother, Ambrose, who founded two scholarships at St. John's. The value of the document is enhanced by the rarity of William Gilbert's autograph, only two others being known—one on a medical certificate addressed to Lord Walsingham, now in the Record Office, the other discovered by Silvanus Thompson in a book which belonged to Gilbert when at St. John's; also by the fact that it is sealed with Gilbert's own signet ring, carrying his crest, a half-eagle with wings displayed. Prof. Liveing, in communicating the discovery to the College, makes this interesting comment. "The spelling of ordinary English words had not crystallized in Elizabeth's reign, much less that of names, and it was certainly [so] common at that time to spell the same name in two or more different ways in one document that I have concluded that it was done purposely so that nothing might turn on the spelling to invalidate it". Colchester has always pertinaciously adhered to the spelling Gilberd, and as it appears thus at the head of this document, the city is apparently justified.

It may be of interest to look for a moment at the background of Gilbert's life in Cambridge and London. In both, active changes were occurring. At the universities, and particularly at Cambridge, the concentrated interest in theology which had formed the main study of scholasticism was declining. The active developments in the State were making a demand for the sons of the gentry to play their part in the social

system of the country and its government. So they went to the university to acquire some general culture. There was a risk that the new enthusiasm for deeper study and research "would be elbowed out of existence by endeavours to gratify the wish for a higher education which would suit a young gentleman desirous of making his mark in some recognized public or professional capacity and which should not take up too much of his time". This risk was materially increased by the introduction of a system by which school and college elections were influenced in favour of the well-to-do against the poor; more especially the best prizes—fellowships—were awarded in obedience to mandates obtained in devious ways from the Court. For the first time a university education had a social value, which led to a different type of student and a more riotous way of living. So much so that Caius, who had done his best to promote the new learning, began to wonder whether his benefactions had been wisely bestowed. It is, by the way, curious that though Caius and Gilbert were contemporaries at Cambridge, separated only by the length of Trinity Street, there is no record of any association between them. It strengthens my expressed belief that Caius was more interested in institutions than in individuals. We can set against this an undoubted spread of a genuine love of learning, while the following century was the most active in the intellectual life of Cambridge until the latter half of the nineteenth. Still, one must admit that in the Elizabethan period there was a change from a home for poor scholars to a more mundane life—a change which has in varying degrees persisted and which this century has been trying to overcome. There is indeed a danger of the pendulum swinging too far the other way.

As to the position of the medical world at that time, A. W. Ward says, "The physician's profession . . . was being disentangled on the one hand from that of the clergyman . . . and on the other hand from the trade of the apothecary . . . and from that of the barber, who united to his main function those of the dentist, and yet others. . . . The pretensions of both physicians and surgeons to a knowledge of which they fell far short were still a subject of severe censure; but little or nothing was said in or outside the profession against what was still the chief impediment to the progress of medical science—its intimate association with astrology".

On these dangers, both at the university and in the medical profession, Gilbert's influence was salutary. His insistence on observation and experiment, his scorn for reliance on mere authority, his hatred for shams and quackery, were not without their effect. In the conditions laid down for the teacher of medicine in the Academy he visualized, but which never came to fruition, it was stated, "He was never to allege any medicine of any kind, but that he was to declare the reason philosophical of every particular, and he was to show how the medicine was made and all the instruments used in making it. . . . The physitian was continually to practise with the Natural Philosopher to try and search out the riddles of Nature." Note here an anticipation of Harvey's injunction. Gilbert has been called the first English Copernican, and without transgressing beyond my particular thesis of Gilbert as a physician, I would urge that this made him particularly suited to combat the pestilential influence of astrology on medicine, from which Jean Fernel of Paris was just emancipating himself.

"Q." has spoken of "men, who with the splendour of the Renaissance in their eyes, supposed themselves to be working all the while upon pale and borrowed shadows". Thus Linacre looked to the past for the revival of learning; Caius faced both ways; but Gilbert steadfastly looked forward, and thus he may be acclaimed the first of English modern men of science, and was so recognized by the succeeding generation. For Sir Thomas Browne described him as the Father Philosopher who discovered more in terrestrial magnetism than Columbus or Amerigo ever did by it, while Dryden said of him, "Gilbert shall live till Loadstones cease to draw".

## CEREAL DISEASES

### By W. C. MOORE

THE important place of cereals in the war-time food production programme, and the urgency of increasing both acreages and yields, have inevitably thrown into prominence the problems of failure and loss through disease. A good deal of attention has been given to these problems during the war years, and the time is appropriate to take stock of the position. For this purpose the Association of Applied Biologists recently devoted one of its general meetings to a symposium on cereal diseases, which was held at the Imperial College of Science and Technology, with the president, Prof. W. Brown, in the chair.

In his introductory remarks Mr. W. C. Moore referred to the surveys of plant diseases organized by the Ministry of Agriculture and Fisheries since 1917. These enable one to form a fairly clear picture of the relative importance of different cereal diseases; but the time is now ripe for concerted efforts to determine the significance of disease more precisely and in terms of loss of yield or in cash value. More than fifty diseases have been listed on cereals in England and Wales, and of these at least seven are of some economic importance—wheat bunt (*Tilletia caries*), take-all (*Ophiobolus graminis* and its var. *Avenae*), eyespot (*Cercosporella herpotrichoides*), yellow rust (*Puccinia glumarum*), mildew (*Erysiphe graminis*), leaf spot of oats (*Helminthosporium Avenae*) and leaf stripe of barley (*Helminthosporium gramineum*). To these must probably be added the various deficiency diseases about which little is yet known. Yellow rust is the most injurious of cereal rusts, but only about once in ten years is it sufficiently bad (as in 1943) to reduce yields by more than an estimated 5–10 per cent. Black rust is usually late and local; but occasionally, probably when large numbers of uredospores are blown over from the Continent in June or July, an epidemic such as occurred in 1940 develops. Bunt bids fair to repeat its behaviour after the War of 1914–18 unless care is taken. In the early '20's about a third of the seed wheat samples were bunted. A steady improvement followed, and in 1940 the figure was as low as 1·2 per cent; but the number of badly bunted crops reported in the last three years strongly suggests that the disease may again be on the increase, in spite of the great advances made in seed dressing. Fortunately, ergot

need give rise to no alarm in Britain. It becomes prominent only when cool, wet weather prolongs the normally short flowering period, and these conditions have been fulfilled very few times in the last twenty-five years.

Those who have not personally studied biologic specialization in fungi are often bewildered by, or even sceptical of, the multiplicity of physiologic races found among rust fungi. All modern British work on biologic specialization in cereal rusts has been carried out under the supervision of Prof. F. T. Brooks, and the authoritative survey he made of the subject was both illuminating and stimulating. The races of each rust are determined by their behaviour on a limited number of differential host varieties in the seedling stage when grown under constant environmental conditions. The complexity of the problem is exemplified by the fact that nearly two hundred physiologic races of *Puccinia graminis tritici* and more than a hundred of *P. triticina* have been defined abroad, chiefly in the United States. Nothing is known about the particular races of *P. graminis tritici* that occur in Britain, but a number have been distinguished in *P. triticina*, *P. anomala* and *P. coronata*. At least two races of yellow rust are found here, and a comprehensive survey for further races is needed after the War in order that the relative susceptibility of common wheat varieties to them can be determined. Certain difficulties are inherent in the work. Genetic purity of the differential races and of the rust cultures is essential, the cultures must be kept in isolation and free from contamination, and constant environmental conditions must be maintained. In view of the extreme biologic specialization in cereal rusts and the possibilities of further changes by hybridization and gene mutation, Prof. Brooks doubts whether further study along the usual lines will be really profitable except in relation to plant-breeding programmes. To the plant breeder the discovery of physiologic specialization is of paramount importance. He need not concern himself with all the races described, for many of them behave as single groups in the field; moreover, the discovery of mature plant resistance has greatly eased matters. None the less, new virulent races may develop at any time, and the position can be safeguarded only by continued close co-operation between pathologists and plant breeders.

Dr. W. A. R. Dillon Weston reviewed the history of cereal diseases in East Anglia during the past twenty-one years and explained how their prevalence and intensity have been influenced by improvements in seed treatment. In 1923 copper sulphate was the chief material used for disinfecting seed wheat against bunt. A few farmers used formalin, and afterwards copper carbonate came into prominence for a time, but in the early '30's these were gradually displaced by the organo-mercury seed dressings. This was an event of outstanding importance. The new compounds provided an effective means of controlling the stripe diseases of barley and oats, which had up to then been responsible for much pre-emergence blight and thin stands. As a result the balance has gradually shifted; leaf blotch of barley (*Rhynchosporium Secalis*), for example, which is not seed-borne and therefore not prevented by seed treatment, has become more noticeable as the prevalence and intensity of leaf stripe has declined. Oat smut, at one time prevalent and intense in most crops, is now less evident. On the other hand, the most recent trials with various organo-mercury dusts have shown that they are not all equally effective, and this aspect of things was considered in its relation to the voluntary scheme, recently inaugurated by the Ministry of Agriculture and the Department of Agriculture for Scotland, for the official approval of insecticides and fungicides marketed under brand names for the control of plant pests and diseases. Particular emphasis was laid on the need to assess the efficiency of the products by field tests. Cereal rusts are not normally serious in East Anglia, and take-all, at one time rampant on many farms, cannot now be considered a major problem.

Dr. R. W. G. Dennis discussed the occurrence of cereal diseases in Scotland, where the position is somewhat different from that in England and Wales. Oats are the most important cereal crop, and the seedling blight phase of leaf spot is still the most important disease—in 1942 more than half of 260 samples of seed taken at random showed from 5–42 per cent infection with Helminthosporium. Tribute was paid to the pioneer work of D. G. O'Brien, whose efforts to put dry seed dressing on its feet in west Scotland had resulted in the sale in 1932 of sufficient organo-mercury dust to dress two million bushels of grain or about half the oats sown in Scotland that year. The use of seed dressings is now general in the west and to some extent in the north, but on the best Lothian soils and elsewhere in the east little benefit is derived from their use, even with heavily infected grain. Species of Fusarium, especially *F. nivale*, and pre-emergence rotting due to soil fungi are also responsible for thin stands of oats sown under poor moist conditions or in wet soils. The virtual disappearance of oat smuts in Scotland occurred before seed dressings came into use and has been attributed to the introduction of 'regenerated strains' of oat varieties and to increased care and selection of seed crops. In the wetter districts of the west and north take-all is prevalent in oats following old pasture and is common elsewhere if oats are taken more than two years in succession. Crown rust is usually scarce, though extensive outbreaks occur at long intervals. Wheat diseases are of little importance apart from eyespot, which is widespread in the Lothians, Fife and Morayshire; bunt is scarcely ever seen and brown rust (*Puccinia triticina*) is unknown in Scotland.

Take-all of wheat is widely distributed in England, but becomes troublesome only in wet seasons and on light soils overlying chalk or limestone, where the rotation is too short. The form on oats is restricted to those areas—Wales, the north-west and north of England, and Scotland—where oats is the chief cereal crop. Mr. S. D. Garrett, whose work on this disease has thrown so much light on the wider and more fundamental problems of root rot caused by fungi, discussed the factors affecting the behaviour of take-all in different soils and seasons. Growth of the runner hyphæ of Ophiobolus along the host roots is favoured by good soil aeration and by an alkaline reaction of the soil. In poorly aerated or acid soils the growth of the hyphæ may be controlled by accumulation of respiratory carbon dioxide at the root surface, with which is associated a reduction in the partial pressure of oxygen. In well-aerated soils carbon dioxide must diffuse rapidly away from the root zone, and in alkaline soils a high proportion of the carbon dioxide is transformed into bicarbonate. Light-textured soils also favour take-all inasmuch as they are usually poor in nitrogen and often other plant nutrients, and deficiency in the

main nutrients hinders recovery from attack by curtailing the production of new secondary roots to replace those destroyed by the fungus. In Australia phosphate is usually the missing nutrient, in England nitrogen. The exceptional severity of the disease in certain southern counties of England in 1942 may have been due in part to leaching-out of nitrates by abnormally heavy rainfall in January. Survival of Ophiobolus in infected root and stubble residues is mainly dependent on an adequate supply of nitrogen from the soil, which encourages fresh hyphal growth.

For some years Miss M. D. Glynne has made a special study of eyespot in wheat and barley, and the account she gave of this disease revealed how closely it is bound up with lodging in these crops. Less eyespot occurs on light, well-drained soils than on heavy, wet ones, and the climate of the west and north of Britain favours attack by it more than conditions in the south and east. Yet, because oats are highly resistant and the disease increases with the frequency of wheat and barley in the rotation, eyespot is more prevalent in the eastern than the western half of southern England. In a thin crop the individual affected straws begin to fall over among the upright ones from the end of June, giving the condition known as 'straggling'. If the affected crop is a heavy one general lodging is likely to take place sooner or later in long-strawed varieties. In a survey carried out in 1941, lodging caused by eyespot was about as common as lodging due to non-parasitic causes. In addition to direct loss from the disease there may be indirect loss as a result of lodging. Experimental work has shown that in a field with about 60 per cent severe infection, yield is reduced by 30 per cent and there is a marked increase in the amount of tail corn; if lodging occurs the loss is much greater or even complete. Such losses can be minimized by sound rotation or by using short-strawed varieties and feeding them well.

Dr. F. R. Immer, professor of genetics in the University of Minnesota, was warmly welcomed as a visitor at the meeting, and in the general discussion that followed he referred briefly to the programme for plant breeding in relation to disease that is now under way in Minnesota. He expressed surprise at the wide differences in cereal disease problems in Britain and the United States; but entered a word of warning against underestimating the real effect and the potentialities of common but apparently harmless diseases.

# NEWS and VIEWS

## Research Fellowships at British Universities

THE directors of Imperial Chemical Industries, Ltd., have offered to provide eighty fellowships at nine universities in Great Britain, to be held by senior workers in certain sciences. The scheme is announced to operate for an initial period of seven years, and the fellowships will be of the average value of £600 a year, though the universities will have power to determine the emolument for each particular appointment. The subjects to which the fellowships are to be devoted are laid down as physics, chemistry and the sciences dependent thereon, including chemotherapy. The administration of the scheme rests wholly with the universities, which will select and appoint the fellows, subject only to such conditions as to duties and tenure as the universities themselves impose. No conditions whatever are attached by I.C.I. to the tenure of these fellowships. The fellows will be members of the university staffs, and will be concerned only with the duties laid upon them by the universities. Their primary work will lie in research; but they must also take some part in university teaching. It is intended not to relieve the universities from the cost of maintaining any part of their normal work, but to enable them to add to what they already do. The universities to which this offer has been made comprise the larger metropolitan universities and those which have a close geographical relation to the main centres of the Company's production. Twelve fellowships have been offered to the Universities of Oxford, Cambridge and London, eight to the Universities of Glasgow, Edinburgh, Manchester, Birmingham and Liverpool and four to the University of Durham.

The purpose of the directors of Imperial Chemical Industries, Ltd., in instituting this scheme is to strengthen the general provision in British universities for scientific teaching and research. It is intended to implement the Company's view that academic and industrial research are interdependent and complementary, and that substantial advances in industry cannot be looked for without corresponding advances in academic science; and the main purpose is the strengthening of university scientific departments in whatever way each university thinks to be best. A rational policy of this character, together with a wise selection of men both as regards capabilities and tenure of office, will lead, it is thought, to the emergence of a body of men capable of taking high academic or industrial positions, thereby advancing academic and industrial research. This it should certainly accomplish, for the scheme is so wide in its scope, and the universities are given so free a hand in its working, that most of the limitations usually inherent in trusts and endowments are avoided. The task is now before the selected universities, while preserving scrupulously their independence, so to select recipients of these fellowships as to justify the belief in the importance of university research which has led to their establishment.

## The Society for Cultural Relations

THE Society for Cultural Relations between the Peoples of the British Commonwealth and the U.S.S.R., known more widely by its briefer title S.C.R., has just completed its first twenty years of activity and has issued a concise and very interesting report on its work during the period. It is difficult now to recapture the atmosphere of 1924, when the sufferings caused by the Revolution and the Civil War were still fresh in people's minds, and only relatively few recognized the importance of trying to understand what was going on in Russia and of breaking down the barriers that threatened to isolate that country from the Western world. A small but distinguished group of people founded the Society and organized an exhibition of Soviet art, books and

magazines; a Science Section was formed under the chairmanship of Sir Richard Gregory and a Press Committee of British and Russian journalists met. Later, various other sections were formed and the Society steadily increased in membership. Each year has seen new developments, and since the War both the status and the influence of the Society have been heightened; it has been recognized that only by keeping exclusively to the one purpose of fostering cultural relations can the Society hope to make a wide appeal. It now has a good library and a panel of lecturers, and it is prepared to deal with inquiries coming within its ambit. We wish the Society continued success in the important and difficult tasks that will confront it in the post-war years.

## Indian Famine Inquiry

THE Government of India has announced the following names of the chairman and members of the famine inquiry commission: Sir John Woodhead, Finance Member of the Government of Bengal 1932–1937, Governor of Bengal during June–November, 1939 (chairman); Mr. S. V. Ramamurti, adviser to the Governor of Madras and formerly director of agriculture, Madras; Dr. W. R. Aykroyd, director of the Nutritional Research Laboratory, Coonoor; Khan Bahadur Mien Afzal Hussain, formerly principal of the Agricultural College, Lyallpur; Sir Manilal B. Nanavati, president of the Indian Society of Agricultural Economics, deputy governor of the Reserve Bank of India during 1936–1941, and an authority on sociological and agricultural problems; Mr. R. A. Gopalaswami (secretary), assisted by Rai Bahadur D. N. Maitra.

## Higher School Certificate Biology

THE content and form of the traditional syllabus for the Higher School Certificate examination are frequently influenced by the older point of view that biology, botany and zoology are intellectual disciplines unrelated to ordinary life, and, further, that anything relating to human beings lies in the province of anatomy and physiology in the medical curriculum. Modern opinion is that such studies are closely interwoven with our own lives and that, while they may serve as an introduction to subsequent professional or university courses, they should also form, because of their method and content, an essential part of the education of the ordinary citizen. Some progress has been made in this direction by slight emendations or re-interpretations of existing syllabuses; but a Joint Advisory Committee for Biology was set up by the University of Cambridge in June 1943 to recast thoroughly the syllabuses for the Cambridge Local and Oxford and Cambridge Schools examinations. The Committee included representatives of the teaching profession and of the University of Cambridge, and also had the advice of one of H.M. inspectors of secondary schools, members of the University of Oxford, the Matriculation and School Examinations Council of the University of London, and the Central Welsh Board.

The resulting syllabuses, quite new in content and outlook, are not regarded as definitive, but criticisms are invited and it is proposed to issue a revised edition if, when they have been given a trial, it is found that modifications are necessary. The syllabus of each subject is fully set out and, in zoology, detailed notes explaining the intention of the various parts of the syllabus are provided. The content is arranged for a course extending over two school years and assumes that 450 periods each of forty minutes are available. A useful feature of the report is that each subdivision of a subject is followed by a suggestion of the approximate number of periods that should be devoted to it. These suggestions, if followed in a reasonable and not slavish manner, should result in a well-balanced course without overweighting particular parts and at the same time allow latitude for individual circumstances. In the opinion of the writer of this note the syllabuses are a welcome improvement on most of those at present in effect and decidedly a move in the right direction, particularly if more attention is given to the individual practical work of the pupils: but—the proof of the pudding is in the eating. Copies of the report can be obtained from the Cambridge University Press, 200, Euston Road, London, N.W.1, price 6*d*. (7*d*. including postage).

## Apprenticeship and the New Education Bill

SOME strong criticisms of the raising of the school-leaving age envisaged under the new Education Bill are given in a recent pamphlet on "Apprenticeship for a Skilled Trade" by Mr. F. Twyman, managing director of the well-known optical firm of Messrs. Adam Hilger, Ltd. (London: Charles Griffin and Co., Ltd. 5*s*. net). Thus he says, "Besides tending towards the disappearance of skilled craftsmen and arresting the development of individual boys, the proposed deferment of the school-leaving age will lessen the productive capacity of the nation just at a time when it should be increased". Mr. Twyman speaks in no uncertain terms against the views of those who seem to regard it as self-evident that, schooling being a good thing, the longer it is continued the better; and he claims that there is a general neglect of the fact that at the age of fourteen many normal boys become impatient of learning unless they see some useful result. He believes that the skilled trades can best be satisfactorily recruited through a scheme of apprenticeship commencing at fourteen years of age under which boys would enter the trade with part-time day release to attend school, varying from two days a week at fourteen to one day at eighteen years of age. The scheme would be based upon the following four main premises: (1) industry needs more good craftsmen; (2) these can only be attained by apprenticeship; (3) the apprenticeship contract must embody a curriculum; (4) independent inspection must be provided to ensure that the terms of the contract are fulfilled.

There is good sense in much of what Mr. Twyman says about the need for realism in modern education, and he would probably be surprised to find that a large number of educationists agree with him; indeed, his proposed scheme of apprenticeship is essentially educational in character, since the young apprentice, instead of wasting his early years in making tea and running errands, would from the start learn practical subjects in the works under strict supervision. Mr. Twyman's essay certainly suggests a valuable scheme for co-operation between school and industry, which should fittingly be examined at the present time.

## Bureau of American Ethnology

IN spite of its increasing concern with the war effort, the Bureau of American Ethnology still manages to carry out some of its normal activities (Sixtieth Annual Report: June 1942 to June 1943.

Pp. 10. Washington: Gov. Printing Office). Although the general policy is not to undertake field work during the War, special circumstances made it advisable to make a preliminary investigation of a site in the Agate Basin, East Wyoming. This yielded points of general Yuma character, but of relatively recent date. Dr. Stirling, chief of the Bureau, took charge of a further National Geographic Society – Smithsonian Institution Expedition to southern Mexico, which continued excavations at La Venta. Publication continued, and it is good to hear that the great "Handbook of South American Indians" is three-quarters complete. Three bulletins were issued, and eight were in the press at the end of the year. Members of the staff were active in promoting inter-American co-operation, and with this end in view the Inter-American Society of Anthropology and Geography was formed. A quarterly journal, *Acta Americana*, is to be issued. Specifically war-like activities comprised the preparation of various Smithsonian Institution War Background Studies and publications of the Ethnogeographic Board, besides the answering of numerous questions from the armed forces.

## Ophthalmological Research at Leeds

On the recommendation of a special committee, the Council of the University of Leeds has adopted a scheme for the establishment of an Ophthalmological Research Centre. As soon as the necessary funds are available, the Council will proceed to the appointment of research fellows to work on special problems concerned with the prevention and cure of blindness and other diseases of the eye. X-ray equipment, the recently installed electron microscope and other facilities will be made available for the work in the University. The maintenance and development of the Centre will be in the hands of an Ophthalmological Research Advisory Committee.

## Officers and Trustees of Science Service

The following have been re-elected officers of Science Service, the American institution for the popularization and interpretation of science: president, Dr. E. G. Conklin; vice-president and chairman of the Executive Committee, Dr. Harlow Shapley; treasurer, O. W. Riegel; secretary, Watson Davis. Dr. Otis W. Caldwell, of the Boyce Thompson Institute for Plant Research and general secretary of the American Association for the Advancement of Science, and Max B. Cook, promotion editor of Scripps-Howard newspapers, have been elected to the Board of Trustees, which is now constituted as follows, the bodies represented by the trustee being indicated in brackets: Dr. Otis W. Caldwell, Dr. Edwin G. Conklin, president of the American Philosophical Society, and Dr. Henry B. Ward, University of Illinois (American Association for the Advancement of Science); Dr. Warren H. Lewis, Wistar Institute of Anatomy and Biology, Dr. R. A. Millikan, California Institute of Technology, and Dr. Harlow Shapley, director of the Harvard College Observatory (National Academy of Sciences); Dr. C. G. Abbot, secretary of the Smithsonian Institution, Dr. Ross G. Harrison, chairman of the National Research Council, and Prof. Hugh S. Taylor, Princeton University (National Research Council); A. H. Kirchhofer, managing editor of the *Buffalo Evening News*, O. W. Riegel, Washington and Lee School of Journalism, now on war leave with the Office of War Information, and Neil H. Swanson, executive editor of *Sun* papers (journalistic profession); Max B. Cook, Frank R. Ford, editor, Evansville Press, and H. L. Smithton, executive agent of the E. W. Scripps Trust (E. W. Scripps Estate).

## Night Sky in August

Full moon occurs on August 4d. 12h. 39m. U.T., and new moon on August 18d. 20h. 25m. The following conjunctions with the moon take place: Aug. 14d. 20h., Saturn 1° N.; Aug. 20d. 03h., Venus 2° S.; Aug. 20d. 19h., Mercury 8° S.; Aug. 21d. 04h., Mars 4° S. In addition to the above, the following conjunctions also take place: Aug. 13d. 13h., Venus in conjunction with Jupiter, Venus 0·6° N.; Aug. 26d. 15h., Mercury in conjunction with Venus, Mercury 6·1° S. Mercury reaches its greatest eastern elongation on Aug. 10. The planet sets at 20h. 38m., 19h. 51m. and 18h. 38m. at the beginning, middle and end of the month respectively. Venus is too close to the sun to be favourably observed, setting about half an hour after sunset during the month. Mars, Jupiter and Saturn are not well placed for observation, though Saturn is becoming visible in the early morning hours, rising about midnight towards the middle of the month. The Perseid meteors reach their maximum on Aug. 10–12.

## Announcements

At a meeting of the Council of the Institute of Fuel, held this month, it was announced that Dr. E. W. Smith has agreed to continue in office as president for a further period of twelve months, that is, until October 1945. It was also announced that the Melchett Medal for 1944 has been awarded to Dr. J. G. King, director of the Gas Research Board, in recognition of the outstanding work he has done in recent years during his long connexion with the Fuel Research Station at Greenwich; and that Mr. H. L. Pirie, one of the honorary secretaries of the Institute of Fuel since its inception, has been made an honorary member.

The following have been elected officers of the Institution of Electrical Engineers for the session 1944–45: *President*, Sir Harry Railing; *Vice-President*, W. J. H. Wood; *Honorary Treasurer*, E. S. Byng; *New Members of Council*, H. Bishop, W. N. C. Clinch, F. C. Winfield, and Dr. R. W. Sillars.

The Chadwick Trustees are offering an award of £250 for an investigation of the reasonable maximum 'density' range (per acre) for small houses with gardens, suitable especially for the intermediate and outer zones of large towns—with due regard to the amenities essential to a comprehensive town planning arrangement. Applications, in writing, must reach the Clerk to the Chadwick Trustees, 204 Abbey House, Westminster, London, S.W.1, before the end of September, accompanied by evidence of qualifications and a brief statement of the general plan of research proposed.

Referring to the review in *Nature* of March 18, p. 327, of "Frontiers in Cytochemistry", the editor, Prof. Normand L. Hoerr, has pointed out that he was incorrectly described as the successor of Prof. R. R. Bensley in the chair of anatomy in the University of Chicago; Prof. Hoerr is professor of anatomy at Western Reserve University, Cleveland, Ohio.

*The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.*

## Marine Biological Research in Great Britain

THE coast-line of Great Britain offers an unrivalled diversity of habitats for the study of marine benthic communities. There is a considerable proportion of rocky shore, including the peculiar facies provided by the chalk of southern England; there are many stretches of sand and shingle and numerous inlets affording specialized habitats of diverse kinds. Can it be said that we are playing our part in the biological exploration of the numerous communities thus available to us? Speaking as a botanist, I would answer this question in the negative.

Apart from the valuable work of Lloyd Williams, Margery Knight and Kathleen Drew, the great advances in our knowledge of the structure and reproduction of seaweeds during the last thirty years are almost entirely due to the activities of Danish, French, German and Swedish workers. On the taxonomic side, also, Great Britain has made no serious contribution, comparable to the monumental work of Sauvageau on Sphacelariales or to Kolderup Rosenvinge's important memoir on the Rhodophyceæ of Denmark. I am not qualified to say how far these criticisms apply also to the benthic fauna.

It is true that a considerable number of papers dealing with the general floristic composition of the benthic communities of seaweeds on various parts of the coast of Britain has been published. One may recognize the value of the preliminary data thus obtained; but it may be doubted whether this work has materially added to our understanding of the nature and composition of these communities, since the publication of Cotton's outstanding memoir on the marine Algæ of Clare Island in 1912. Certain of the papers published during the last twenty years have been concerned with the effects of diverse environmental factors, in particular those affecting the littoral communities. More important advances in these directions have, however, been made by Continental workers.

Much of the floristic work is rendered less valuable by the complete or almost complete absence of data regarding diatoms, which play an important part in many littoral and sublittoral communities. Little information is available as to their time of occurrence and distribution, or the part that they almost certainly sometimes play as colonizers. Moreover, the communities occurring near and above high-water mark have usually been but imperfectly studied, despite the biological interest attached to the specialized conditions of their habitat. The only detailed investigation of such communities, so far as I am aware, is that of Anand on those inhabiting the chalk cliffs of southern England. Greater progress has been made with studies on the floristic composition and conditions of existence of the algal flora of salt-marshes, thanks to the excellent work of Sarah Baker and Nellie Carter.

The interrelations of fauna and flora in the benthic zone are subjects of great biological interest. An approach to this aspect of marine ecology has been made by a number of workers in Great Britain, more particularly by zoologists. In the absence of evidence of assistance from a competent algal taxonomist one may feel some degree of diffidence in accepting as complete or altogether reliable the data offered on the floristic side; moreover, as with the purely floristic studies, diatoms are in general left out of the picture. In any event these investigations have scarcely got beyond the fringe of the problems involved. Attention may also be directed to the need for a more comprehensive study of British marine fungal parasites than has hitherto been undertaken.

For the most part the diverse researches referred to above have been carried out by biologists working in universities remote from the site of their investigations. The latter have been effected by means of periodical visits, and all credit must be given for the more or less successful surmounting of the difficulties that are inherent in discontinuous work of this nature. No real progress is, however, to be expected until far better facilities than those at present existing become available. In particular, it is essential that a lead to the investigation of the benthic flora and fauna of the sea be given by an established group of workers, permanently in touch with the problems and expert in special aspects of marine biology. The investigation of the ecological problems that await solution demands a team of workers which should include one or more zoologists, as well as at least two botanists specializing respectively in seaweeds and marine diatoms. Afterwards, one or more physiologists will have to join the team to aid in the solution of the diverse problems relating to growth, nutrition, etc., that will arise. Once such a centre had been firmly established, its activities would rapidly expand by the attraction of research workers from the universities.

It is natural to look to the Laboratory of the Marine Biological Association at Plymouth as the best centre for the development of such work. The very high reputation of this Laboratory and of the members of its staff would encourage the performance of work at a high level of achievement. So far, however, the fundamental research carried on there has been directed in the main to investigations dealing with the pelagic life of the sea, research which has led to results of outstanding scientific importance. If the Plymouth Laboratory is to undertake also the investigation of the marine benthos, a courageous policy will be necessary. To restrict unduly the number of workers detailed for this aspect of marine biological investigation or to limit the necessary facilities would cramp the work at the outset and as likely as not result in failure. In view of its bearings on the elucidation of general biological principles and its possible economic importance, it may not be looked upon as a mere appendage of the work hitherto carried on at Plymouth.

Should other considerations not render feasible such an extension of the scope of the work of the Plymouth Laboratory, it would be better to concentrate research on marine benthic plants and animals at an altogether separate centre. For such a purpose one of the other marine stations already in existence or one of the maritime universities can be envisaged. Alternatively, since it is to be hoped that similar centres may be established in one or more parts of the Empire, especially in the tropical zone, the University of London might appropriately consider the foundation of such a station.

# Self-recovery in Metals

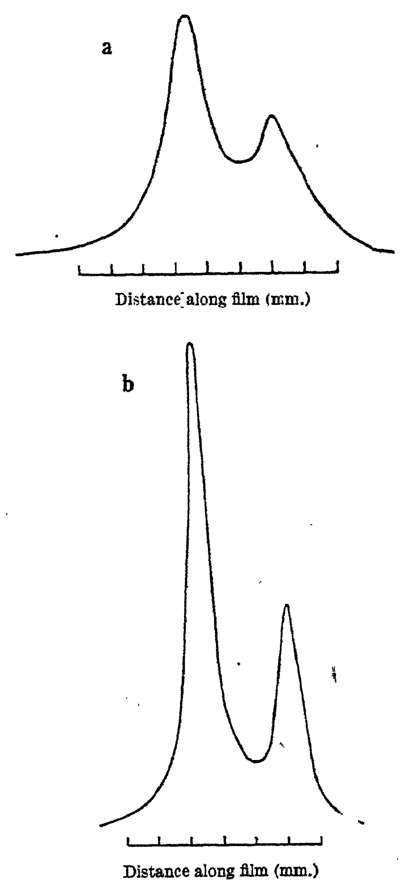
Two theories have been put forward to account for the broadening of the X-ray reflexions given by cold-worked metals. First, the crystals may be broken down into small mosaic elements (fragmentation)[1], or, secondly, they may be so distorted by the stresses (microstresses) present that the lattice parameter varies over a range of values[2]. Recent work seems to indicate definitely that in the case of copper[3], tungsten and α-brass[4] the major part of the broadening is due to the latter effect.

Although it would seem reasonable to extend these results to all metals, a difficulty arises in the case of those such as aluminium which give sharp lines when cold-worked. On the fragmentation theory this would correspond to an unusually large value of the limiting crystallite size; on this account it has been claimed[5] that aluminium is 'self-recovering' at room temperature, the implication being that after cold-working the crystal grains increase so much in size that the broadening they produce is negligible. The microstress theory, however, cannot produce such a ready explanation; at first sight it would seem necessary to assume that no appreciable stresses were present in the cold-worked metal, and this is not in agreement with the known mechanical properties.

Some contribution towards the solution of this problem has been given by the observations of Wilson[6] and Spillett[7] that the broadening of the X-ray lines given by cold-worked aluminium sheet is not negligible. We have verified that this is also true for filings; the accompanying figure shows photometer curves, derived from photographs taken in a 19 cm. diameter camera, for line 420 for unannealed and annealed filings, and it will be seen that there is a considerable difference between the two although the α-doublet is clearly resolved in each case.

It only remains to show that the broadening is of a reasonable order of magnitude. In order to do this, we have compared it with the broadenings given by several other cold-worked cubic metals, and have derived the corresponding value of the internal stress $T$ in each case. We have used the relation $T = E\beta\cot\theta/4R$, where $E$ is Young's modulus, $\beta$ is the measured broadening, $\theta$ is the Bragg angle and $R$ is the radius of the camera. $E$ depends on the indexes of reflexion, but for the present purpose it may be considered as a constant.

| Metal | Indexes of reflexion | Radiation | $\beta\cot\theta$ (mm.) | $T$ | Ultimate tensile stress |
|---|---|---|---|---|---|
| | $h\ k\ l$ | | | $10^8$ dynes/cm.$^2$ | |
| Iron | 2 1 1 | Iron $K\alpha$ | 1·11 | 58·7 | 30–80 |
| | 2 2 0 | | 1·12 | | |
| Nickel | 3 3 1 | Copper $K\alpha$ | 0·97 | 53·2 | 35–120 |
| | 4 2 0 | | 0·96 | | |
| Copper | 3 3 1 | Copper $K\alpha$ | 0·64 | 23·5 | 23–47 |
| | 4 2 0 | | 0·79 | | |
| Silver | 3 3 1 | Cobalt $K\alpha$ | 1·06 | 22·2 | 23–36 |
| | 4 2 0 | | 1·11 | | |
| Aluminium | 3 3 1 | Cobalt $K\alpha$ | 0·15 | 3·0 | 6 |
| | 4 2 0 | | 0·17 | | |
| Lead | 5 3 1 | Nickel $K\alpha$ | 0·20 | 0·7 | 1·2–2·1 |
| | 4 2 2 | Iron $K\alpha$ | 0·16 | | |



PHOTOMETER CURVE OF THE 420 LINE FROM (a) FILED ALUMINIUM, (b) ANNEALED ALUMINIUM, WITH COBALT $K\alpha$ RADIATION. THE SCALES FOR ORDINATES OF THE CURVES HAVE BEEN CHOSEN SO AS TO MAKE THE AREAS EQUAL.

The accompanying table shows the values of $T$ for silver, copper, nickel, iron, aluminium and lead, and for comparison are given the values of the ultimate tensile stress for these metals[8]. It will be seen that in each case the two are of the same order of magnitude. Even for lead, which is also supposed to be 'self-recovering' at room temperature, there is a broadening of the X-ray lines of about the right amount.

It does not follow from these results that recovery does not occur in these metals at room temperature; this can be decided only by photographs taken at different times after filing. We have taken such photographs of the metal specimens described above, with the following results.

(a) Iron and nickel showed no appreciable change over several weeks.

(b) Copper and silver showed quite striking changes; the diffraction broadenings decreased to about half their original values, the α-doublet becoming quite clearly resolved. The change in copper occurred over an interval of about a week and we have followed these changes in detail; but the only data we have about silver are that the X-ray lines were sharper after an interval of several months.

(c) Aluminium and lead also showed some change, but in these cases the broadening is so near the limit of experimental error that the effect is not so clear as for silver and copper.

These results cannot be taken as applying to metal in forms other than filings; X-ray photographs of a piece of hammered copper wire, for example, showed little change after several weeks at room temperature.

We hope to publish elsewhere a more detailed account of this work.

## Energy of Viscosity as a Measure of the Cohesion of Liquids

THE viscosity of a liquid can usually be represented by

$$\eta = A.e^{E_{\text{visc.}}/RT},$$

where $\eta$ is the viscosity; $A$ is a constant; $E_{\text{visc.}}$ is the energy of viscosity; $R$ is the gas constant; $T$ is the absolute temperature. In connexion with other work, it was deduced that the energy of viscosity should equal the work of cohesion for unassociated and non-metallic liquids. The work of cohesion has been defined by Harkins[1] as the energy required to form a surface in a liquid and is equal to twice the surface energy. Now if both the energy of viscosity and the work of cohesion are expressed as calories per mole, they are nearly equal for unassociated liquids.

| At 20° C. Substance | $E_{\text{visc.}}$ cal./mole | Work of cohesion cal./mole |
|---|---|---|
| *n*-octane | 2,040 | 1,928 |
| *n*-hexane | 1,815 | 1,920 |
| Benzene | 2,515 | 2,322 |
| Acetone | 1,668 | 1,676 |
| Carbon tetrachloride | 2,510 | 2,290 |
| 1,2 dibromoethane | 2,790 | 3,056 |
| 1,2 dichloroethane | 2,320 | 2,394 |

For associated and some polar substances the energy of viscosity is greater than the cohesional work. The factor connecting the two quantities varies between 1·5 and 3·5.

| At 20° C. Substance | $E_{\text{visc.}}$ cal./mole | Work of cohesion cal./mole |
|---|---|---|
| Methyl chloride | 1,592 | 948 |
| Methyl alcohol | 2,475 | 1,076 |
| Ethyl alcohol | 3,290 | 1,380 |
| *n*-propyl alcohol | 4,390 | 1,610 |
| Water | 4,150 | 2,020 |

The values of $E_{\text{visc.}}$ were obtained by graphical differentiation of the ln $\eta$ versus $1/T$ curves, while the work of cohesion was calculated as twice the surface energy of one mole occupying the surface according to the equation:

$$E_s = 2{\cdot}39 \times 10^{-8}.\gamma.V^{2/3}.N^{1/3},$$

where $E_s$ is the surface energy in calories per mole; $\gamma$ is the surface tension in dynes per cm.; $V$ is the molar volume; $N$ is Avogadro's number.

Now if the energy of viscosity equals the work of cohesion, it should be proportional to the energy of attraction between molecules. According to prevailing views[2], the attraction between non-polar molecules is inversely proportional mainly to the sixth power of the distance separating the molecular centres. The attraction between polar molecules is said to be inversely proportional to the third power of that distance. The relationship between $E_{\text{visc.}}$ and the distance between the molecular centres was tested by plotting log $E_{\text{visc.}}$ against log $1/r$, where $r$ is the separation of the molecular centres and can approximately be deduced from the molar volume. The slope of the curve of log $E_{\text{visc.}}$ v. log $1/r$ should have a value of 6 for non-polar substances and a value of 3 for polar substances. *n*-Pentane gave a value for the slope of approximately 5·52; 1,2 dibromoethane a value of 5·75; carbon tetrachloride a value of 6·03. On the other hand, methyl chloride, which is a polar substance, gave a slope of 2·89.

Thus $E_{\text{visc.}}$, the energy of viscosity, equals the work of cohesion in the case of unassociated substances and is quite generally a measure of the attraction between molecules.

## Existence of Time-Dependence for Interfacial Tension of Solutions

IT has been known for some time[1,2] that the surface tension (air–liquid boundary) of aqueous solutions of long-chain compounds decreases slowly over a period of many days before an equilibrium value is reached. This slow decrease cannot be attributed to diffusion of the solute to the surface, for with the usual values of the diffusion coefficient the calculated time of the change should be a very small fraction (about $10^{-7}$–$10^{-9}$) of the observed time[1,3]. With a solute in the aqueous phase, adsorbed at an oil/water boundary, the interfacial tension has been found to reach its equilibrium without a time-lag[3], and it has been commonly assumed that interfacial tension (as distinct from surface tension) is not subject to this slow change.

We have measured interfacial tensions at the interface between water and solutions in hexane of long-chain amphipathic substances. Experiments by a precision drop-weight method[4] showed that the interfacial tension varied with time. The variation has been studied by means of measurements made by the pendent-drop method[5], which allows continuous readings to be made without disturbing the surface.

The interfacial tension has been found to fall, rapidly at first and then more slowly, reaching an equilibrium value after some days. This fall is much slower than can be explained by diffusion to the surface. With lauric acid as the solute, a diffusion

coefficient as low as $10^{-22}$ cm.$^2$ sec.$^{-1}$ would be required, instead of the actual value of about $10^{-5}$ cm.$^2$ sec.$^{-1}$. The diffusion to the surface is therefore followed by a process of high activation energy to produce the final state of the surface film. In confirmation of this, the rate at which the final interfacial tension is reached has been found to increase sharply with rising temperature.

The presence of electrolytes in the aqueous phase has been found to alter the interfacial tension – time variation. With this system, where the electrolyte is in a different phase from the surface-active solute, it can exert a direct influence on the interface without altering the diffusion-rate, degree of aggregation, etc., of the solute in the oil phase.

By expanding and contracting the pendent drop, the closeness of packing of the molecules adsorbed at the interface could be varied and $F$–$A$ curves obtained. The interfacial films behaved like insoluble surface films, since a compression of the film did not drive molecules back into solution. Therefore the activation barrier affects desorption as well as adsorption of molecules.

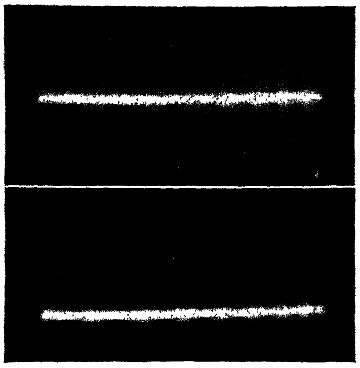
## Light-Effect in Chlorine under Electrical Discharge: Change of the Wave Form due to Irradiation

Previous work on this phenomenon[1,2,3] showed that a current decrease $\Delta i$ is produced by irradiation of chlorine and other gases referred to the rectified mean r.m.s. values of $i$ under different conditions; changes in the corresponding current-structure and its time-delineation are revealed by a cathode ray oscillograph[3]. An iron core step-down transformer was introduced in series with an A.C. indicator. Its secondaries were connected to one pair of the deflecting plates in the oscillograph; the other pair was connected to the time-sweep potential. With but a moderate amplifier gain on each of the plate pairs and the usual adjustments, the oscillograph revealed, besides the frequency of the A.C. supply, a remarkably large number of higher frequencies of widely varying strengths; they were not transients but repeatable and characteristic constituents of $i$ the discharge current. It was also striking to observe the sensibly instantaneous and reversible diminution of the amplitudes of these component frequencies, on irradiating the discharge tube, as shown by a typical pair of oscillograms reproduced herewith.



Exposure, 2 min.

It was observed[1,4] that the production of a change under electrical discharge, chemical or otherwise, for example, the hydrogen chlorine reaction, the activation of nitrogen, its deactivation, etc., requires a minimum threshold potential $V_m$ characteristic of the reaction, its operative conditions such as the frequency $n$, the temperature, etc. At $V_m$, the wattage dissipated in the system and $i$ show a rapid rise as $V$ is increased. In elementary gases, $V_m$ may be identified with or related simply to the corresponding Paschen potential. Below $V_m$, the oscillograph showed a markedly simple current-structure; further, changes of the amplitudes due to the light-effect were not detected. It is considered that ionization by collision in fields due to the applied potential is a necessary condition for the occurrence of this phenomenon. It is found that both for the light-effect and the above type of reactions, $V_m$ diminishes as $n$ is increased; its influence on the light-effect expressed as $\Delta i/i$ is also in the same direction.

An examination of a number of oscillogram pairs like those reproduced, obtained under different conditions, showed that the proportionate reduction on irradiation of the component amplitudes was fairly uniform. These higher frequencies in $i$ represented both the audio and radio ranges. When the latter were eliminated with a series of H.F. filters, the light-effect in the residual audio range was similar to that for the total or unfiltered current. That the above remark applies also to the radio range was indicated by similar results for the light-effect $\Delta i/i$ observed, with and without an amplifier, for $i$ picked up by a moderate size aerial 1–9 ft. distant from the chlorine tube.

## Lanosterol

The problem of the origin and chemical nature of lanosterol—the characteristic substance so far observed only in the wool-grease of the sheep—was originally solved by classifying it as a sterol. Recent evidence[1,2] indicates a more probable connexion with the tri-cyclic terpenes such as α-elemolic acid and with the minor yeast sterol cryptosterol.

Among the oxidation products of cryptosterol are a number of ketonic derivatives which are yellow in colour, probably due to the presence of a chromophore grouping such as $-CO-C=C-CO-$. Ruzicka[3] has lately obtained similar yellow compounds, for example, acetyl-*iso*-elemendionol acid ester, from the

elemolic acids. In continuation of our work on lanosterol[4], we have also isolated a series of yellow ketonic products by the oxidation of lanosterol and its esters with ozone, and with chromic acid. These derivatives include a diketo-alcohol, $C_{30}H_{46}O_3$, m.p. 145°, the corresponding triketone, $C_{30}H_{44}O_3$, m.p. 110° and a compound $C_{27}H_{40}O_4$, m.p. 203°, of which an account will shortly be published.

The formation of these compounds further supports the relationships mentioned, and if the connexion of lanosterol with the tri-terpenes is established, the production, by animal metabolism, of a structural type characteristic of the plant world will provide a problem of biochemical interest.

## Mitochondrial Origin of Cytosiderin (Iron Pigment) in the Liver of Human Pellagrins

DURING the past fifty or sixty years, attempts to reconcile the massive accumulation of iron in various cells and tissues in the body with altered hæmoglobin has led to the universal adoption of the terms 'hæmo-siderosis' and 'hæmochromatosis'. This terminology has focused attention on the metabolism of hæmoglobin and its derivatives, to the exclusion of the consideration of other potential sources of this iron pigment. However, in hæmochromatosis, almost all investigators are agreed that there is no evidence of increased blood destruction to account for the intracellular iron pigment.

By using an improved liver biopsy method, we have studied the liver at the time of admission and during therapy of seventy-six non-European pellagrins, of whom twenty-one were children less than seven years of age and fifty-five adolescents or adults. To date, two hundred biopsies have been performed without any fatalities.

The excellence of the biopsy material allowed us to perform numerous cytochemical studies. In every single liver of the adult and adolescent pellagrins, we noticed, *inter alia*, masses of iron-containing pigment at one stage or another while the cases were under observation. In fact, we regard iron pigment in the liver cell as a constant feature of pellagra in adults, but in children thus far it has not been found under the age of nine years.

The iron pigment arises within the liver cell, appearing first in a region located between the nucleus and the biliary pole of the cell, and corresponding to the position occupied by the Golgi apparatus. Since the pigment arises within the cell, we have named it 'cytosiderin' to distinguish it from the iron pigment derived from hæmoglobin.

By a modification of techniques, we demonstrated simultaneously iron-containing pigment and Sharlach-staining fat in one section, and iron, fat and mitochondria in another. Using such ideal preparations, we felt reasonably certain that the granules of cytosiderin developed from mitochondria which passed through a lipoprotein stage to form combined and free iron. In this transformation the pigment undergoes a series of colour changes from reddish orange to brown or black. All these differently coloured granules contain iron which can be clearly demonstrated by a modified Prussian blue reaction. There is also a reciprocal relationship between the amount of cytosiderin and mitochondria in the cell.

Cytosiderin may be deposited in the liver cells during therapy and may disappear later, or it may be formed in such amounts that the affected liver cell is filled to capacity, disintegrates and liberates its pigment into the sinusoids. Much of it is carried by the Kupffer cells and other histiocytes. The cytosiderin is carried to the portal tracts, and when there is extensive hepatic cytosiderosis, the lymph glands in the porta hepatis and neighbouring regions assume a deep brown colour. With the progress of this disease the portal tracts become thickened, leading ultimately to typical pigment cirrhosis.

We have observed in the same pellagrous patient the complete evolution of pigment cirrhosis from a diffusely fatty liver.

While there is no sexual difference in the incidence of cytosiderosis pigment, cirrhosis is much more common in males.

The demonstration by us that iron pigment may be liberated from intracellular elements, and that cytosiderin may accumulate to such an extent as to lead to pigment cirrhosis, justifies the acceptance of our suggested nomenclature of cytosiderosis as a substitute for hæmochromatosis.

Quite apart from this significant association of cytosiderosis and pellagra, the intimate relationship between fat, cytosiderin, and mitochondria is especially noteworthy. Further studies of these cytoplasmic elements in nutritional deficiencies associated with fatty or cirrhotic livers may lead to a more precise appreciation of the sites of action within the cell of some of the amino-acids, lipotropes and vitamins.

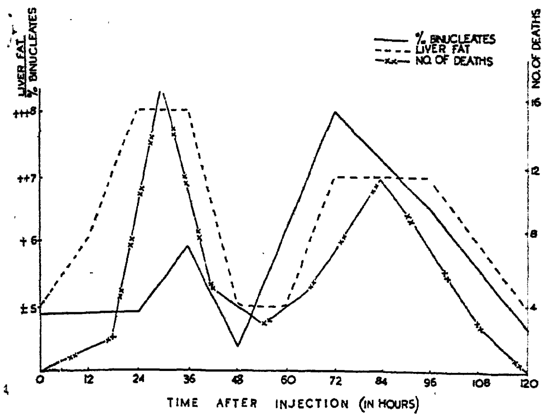
## Rhythmic Changes in the Rat Produced by a Single Injection of Chloroform

DURING the progress of an investigation into the effects of various toxic drugs on the cytology and histology of the liver, it was found that after a single injection of a sub-lethal dose of chloroform (0·5 c.c. of 10 per cent solution of chloroform in liquid paraffin) into male rats, the Scharlach R stainable fat in the liver appeared and disappeared in a rhythmic fashion.

Appearing within 12 hours after the injection, the fat gradually increased to reach a very marked concentration between 24–36 hours. Thereafter it rapidly disappeared, falling to a minimum at 48 hours. Little fat was to be seen during the next 12 hours, but between 72 and 96 hours fat was again very abundant, and then disappeared once more. Moreover, the incidence of binucleated cells in the livers increased and decreased together with the fat,



GRAPH SHOWING VARIATIONS IN LIVER FAT, NUMBER OF BINUCLEATED CELLS AND INCIDENCE OF DEATH AFTER A SINGLE INJECTION OF CHLOROFORM.

so that a corresponding binucleate rhythm was obtained.

An identical fat rhythm was also observed in the kidneys of these animals, whereas in the adrenals a rhythm was again found[1], but in this case the fat concentration varied inversely with that in the liver and kidney. Thus peaks in the fat content of liver and kidney corresponded with minimal amounts of fat in the adrenals.

A similar rhythm was observed in guinea pigs. While working on the guinea pigs, it was noted that animals fatally poisoned (4 c.c. of 20 per cent solution of chloroform in liquid paraffin) usually died within 24–36 or 72–96 hours after treatment. Thus of fifty guinea pigs injected with this dose, seventeen died within 24–36 hours, twelve within 72–96 hours and eighteen died either between 36–72 or 96–120 hours; that is, 58 per cent of animals died either within 24–36 or 72–96 hours, 6 per cent survived and the remaining 36 per cent were distributed over all the other intervals giving a U-shaped distribution curve (see graph).

In connexion with these periods of maximum death-rate, it is important to note that Heyd[2], in an analysis of fatalities following biliary tract surgery in man, noted that acute hepatic deaths occurred either 18–36 hours or 4–7 days after operation.

It thus transpires that in response to certain types of injuries there is a rhythmical reactivity involving at least the liver, kidneys and adrenals, in rats, guinea pigs and probably in man. After chloroform poisoning in guinea pigs and rats, this reactivity expresses itself, so far as the liver is concerned, as rhythmic changes in the amount of fat and the number of binucleated cells. There are two distinct periods in this rhythm which are indicated by maximal fat in the liver and kidney, minimal fat in the adrenal and a rise in liver binucleates.

At these periods after the injection of a single dose of chloroform the resistance of the animal is at a minimum, and death is most likely to supervene.

## 'Fluorine-like' Action of Various Substances on the Teeth

IT has recently been reported that various substances besides fluorine are capable of producing altered incremental lines in the dentin of rats' incisor teeth. Weinmann[1] has shown that strontium, injected as strontium chloride, will cause a hypercalcified line in the dentin forming at the time of injection; the effects on enamel formation were much slighter. Wessinger and Weinmann[2] have further shown that manganese and boron have similar effects on both dentin and enamel.

In a previous communication[3], I showed that fluorine would produce an incremental calcified line in the predentin of rats on diets with a low calcium–phosphorus ratio. In a further paper[4], this effect was analysed and it was pointed out that this procedure might form a simple method of testing the effects of other substances on tooth calcification. Certain other substances have now been examined both on rats on normal ratio diets (Ca : P = 1·46) and also on diets with a low ratio diet (Ca : P = 0·27).

Young animals on the normal diet were injected subcutaneously with the substance investigated and killed after two days. This interval was chosen because two days after injection with fluorine, the calciotraumatic line, hypo- and hyper-calcified zones are very clear and easily measured. The following substances were given: sodium fluoride, potassium oxalate, sodium citrate, manganese sulphate, calcium chloride, strontium chloride, disodium hydrogen phosphate, magnesium chloride, sodium molybdate, aluminium chloride, beryllium nitrate, lead nitrate, borax. The dosage was between 100 and 200 mgm. of the element concerned, per kilogram body weight, in all cases where the animals would tolerate this. In some cases (fluorine, beryllium) the dosage had to be greatly reduced. The amounts of oxalate and citrate injected were equivalent in calcium combining power with the fluorine injected.

The results obtained showed that, at any rate in rats on normal diets, a great many substances could produce results similar to those of fluorine. In no case, however, was any effect on the organic enamel found. The following produced a typical fluorine-like effect in the dentin: oxalate, manganese, calcium, phosphorus, magnesium, molybdenum and beryllium; measurements showed that the effects were caused, as with fluorine, at the time of the injection. Strontium and aluminium produced reactions, but unlike those of fluorine; the strontium reaction was a complete cessation of calcification in parts of the dentin. The following had no effect: citrate, lead, boron.

The animals on the low ratio diet were transferred to this diet when between 50 and 60 gm. in weight, and were kept on it for 28 days. They were injected with the same substances (except magnesium chloride) and killed four days later. At the end of four days the fluorine line in the predentin is about 30 $\mu$ from the odontoblasts and can be well seen.

The results, using this technique, appeared to be much more selective. Apart from fluorine itself, the only other element which gave an identical continuous line in the predentin was phosphorus. Oxalate and manganese gave faint fragmentary lines. No effect was noted in the dentin or predentin with any of the other substances save calcium, which caused the same healing process to begin as occurs if the ratio of the diet is adjusted[5]. Tetany occurred in the animals

after injection of fluorine, oxalate, citrate, phosphorus and molybdenum. None of these substances, except fluorine, caused any change in the organic enamel.

While these results need considerable expansion, certain interesting points arise from them. While fluorine acts on both enamel and dentin, the other elements that imitate its action act only on the dentin. It has been already shown[4] that the action of fluorine on the enamel is independent of the calcium–phosphorus ratio of the diet but that on dentin depends on the calcium–phosphorus ratio, and it would appear possible that the first action is a direct one on the enamel organ, the second indirect, by altering the concentration of blood constituents. If this is true, then it would also be safe to conclude that the other substances here examined also act not only by altering the composition of the blood but have no direct action on the tooth. In any event it would be unlikely that such a diverse number of substances would act directly on the tooth, but they are all such as might affect calcium or phosphorus metabolism. It is interesting to note that with low ratio diets, tetany is not a requisite for the calcifying action in the predentin. Citrate in particular caused violent tetany, but had no effect on the tooth.

To summarize, it is possible experimentally to affect organic enamel and predentin formation separately or together. On normal ratio diets, fluorine affects both; on high ratio diets, fluorine affects only organic enamel formation; while on low ratio diets, phosphorus, and possibly other substances, affect only predentin formation.

## Artificial Production of Monstrosities in the Rabbit

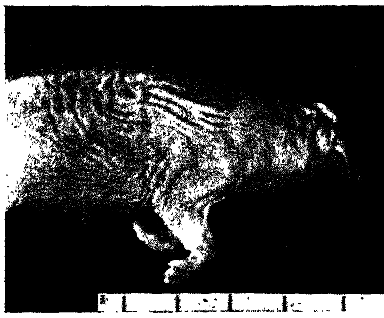

FIG. 1.

FIG. 2.

FOUR doe rabbits of unknown breeding were inseminated with the spermatozoa of one male suspended in a solution of 0·1 per cent colchicine in 0·9 per cent sodium chloride. Doe No. 8 gave birth to six normal young and one monster (Fig. 1). No. 13 gave birth to ten normal young; but on the following day was discovered devouring an eleventh, the normality or abnormality of which could not be determined. No. 14 gave birth to eight normal and one monster (Fig. 2). No. 16 gave birth to five normal and one with unclosed anterior fontanelle (Bregma) and with very small philtrum. This lived only five days. The experimental animals gave, therefore, twenty-nine normal young, two definite monsters, one defective young and one uncertain. In previous inseminations the same does had given fifty-nine young without abnormality. Since February, forty does of similar origin but also unknown heredity had produced 425 young from spermatozoa suspended in 0·9 per cent sodium chloride and no abnormalities had been observed.

In extensive rabbit breeding in Cambridge, similar monstrosities have not been observed. It seems therefore most probable that these monsters were produced by the colchicine, although it will be necessary to repeat the experiment on a larger scale and with inbred strains of known heredity in order to make quite certain that the results are not due to chance.

If attributable to the colchicine, it is likely that the effect is due to polyploidy or some disturbance of the nuclear mechanism or organizers in the tissues affected.

The effects of colchicine may be due to the substance being carried into the ovum by the spermatozoan, or being present in the oviduct and uterus and affecting the fertilized ovum at a later stage of development. Pincus and Waddington[1] treated fertilized ova *in vitro* with colchicine and other chemicals, and concluded that colchicine appears to be especially effective not only in preventing spindle formation and cytoplasmic cleavage, but also in inhibiting the normal movements of the pronuclei; tetraploid ova produced, failed to cleave over a culture period of one day, and the few that did cleave did so at a subnormal rate. Polyploidy has been produced artificially in insects and amphibian larvæ, but not so far as I am aware in mammalian embryos. Further systematic experimentation is planned in the hope that it may throw some light on the causes of embryonic monstrosities.

## Wöhler's Work on Urea

IN his interesting article on Wöhler's work on urea[1], Dr. Douglas McKie states that words spoken by W. v. Hofmann in 1882 in his obituary of Wöhler have given rise to a legend that Wöhler synthetized urea, thereby sounding the death-knell of the hypothesis of vitalism. I do not think any such legend exists.

It is well known that Wöhler arrived at urea through transformation of ammonium cyanate. There is no other interpretation of this fact, therefore also no legend. Dr. McKie bases his attack on

Hofmann on the grounds that a synthesis is only a synthesis if the compounds are built up from the elements. I would like to point out quite shortly that there are synthetic dyes, synthetic drugs, synthetic perfumes, etc., and we know that these products are produced neither in laboratories nor in factories from the elements. Terminology allows also synthetic precious stones, biosynthesis, etc., and has not followed Dr. McKie's exact definition. I admit that Wöhler's method for the production of urea might be more correctly termed a transformation than a synthesis; for in the year 1828 Wöhler was unable to produce urea either practically or theoretically from its elements. But in 1882, the situation had already changed, and Hofmann had a certain amount of justification in speaking of a synthesis.

The second legend, which Dr. McKie wishes to destroy, is that Wöhler's achievement sounded the death-knell of vitalism. I, for one, have never heard of this legend. Indeed, it is well known that even about twenty years after Wöhler's discovery, both Berzelius and Gerhardt, as well as many others, clung to the idea of the *vis vitalis*.

Had Hofmann's obituary of Wöhler been the only source for Wöhler's work and its consequences, he might have been considered to have originated such a legend; but this was not the case. One must also not forget, while criticizing Hofmann's words, that they occurred in an obituary, and not in a scientific dissertation, that they originated from his deep regard and respect for his great colleague and fellow countryman, who at the same time was one of the greatest chemists of his age.

P. MENDELSSOHN BARTHOLDY.

Oxford.

*Nature*, **153**, 608 (1944).

---

It is curious that, in discussing this matter[1], Dr. D. McKie should make no reference to the classical experiments of Scheele. Out of consideration for space, I will do no more than quote the comment of Graebe[2] on the passage, cited by Dr. McKie, in which Wöhler questioned the significance of his preparation of urea:

"Dieser Einwand war aber schon durch Scheeles Versuche wiederlegt, da dieser das Cyankalium nicht nur mittelst Kohle, sondern auch mittelst Graphit erhalten hatte. Auch teilte im Jahre 1828 Desfosses mit, dass beim Überleiten von Stickstoff über ein zur Rotglut erhitztes Gemenge von Ätzkali und Kohle sich Cyankalium bildet. Inbetreff des Ammoniaks waren auch schon die Reaktionen bekannt, nach denen der Stickstoff der Luft sich in Saltpetersäure überführen und diese sich du Ammoniak reduzieren lässt."

---

The legend that I refer to appears in various textbooks and histories of chemistry and in works on general science. I have just read it in more than a dozen of them consulted at random. The sense in which I used the term 'synthesis' is neither personal nor *ad hoc*, and it is the same as that used by Hofmann when he wrote "der Aufbau des Harnstoffs aus seinen Elementen" in the quotation that I gave. My criticism of Hofmann did not, and could not, derive from any difference in the interpretation of this term, but from his statement that Wöhler built up urea from its elements and that the intellect of the time hailed his unification of chemistry with joy, which is untrue in every detail.

Hofmann made this statement in no hasty ephemeral tribute, but in a long contribution filling 164 pages of the *Berichte*. However, although there are reflexions of his words among later writers, I did not actually ascribe the origin of the legend to him. Still, if there should be any doubt about Hofmann's views after what I have already quoted, let us turn to the Faraday Lecture for 1875, a discourse on Liebig given by Hofmann before the Chemical Society of London:

". . . in 1828, Wöhler had demonstrated the possibility of building up from its elements this very urea, the formation of which, up to that period, had been supposed to take place exclusively under the influence of vitality—an experiment ever memorable, since it removed at a single blow the artificial barrier which had been raised between organic and inorganic chemistry."

This is not history, but nonsense.

Scheele's experiments are not classical in the history of the synthesis of organic compounds. In his researches on the colouring principle in Prussian blue (1782–83), the great Swedish chemist incidentally prepared, by the interaction at red heat of either charcoal or plumbago with potash (from vegetable sources) and sal ammoniac (from animal sources), the substance now known as potassium cyanide. Two of his reactants were derived from organic sources; their syntheses had not then been effected; and, moreover, it was not known at that time that the cyanogen group occurred in living matter. Scheele's production of potassium cyanide has therefore no historical significance in this field, and further comment on Graebe's statement is unnecessary.

## The Cedar Tree

The cedar tree to which Mr. Alexander L. Howard refers[1] on p. 597, and before him the Rev. C. A. Jones, is Bernard de Jussieu's cedar tree in the Jardin des Plantes, Paris; it was planted in October 1734. Jussieu had been given the seed for it by Dr. William Sherrard, the distinguished patron of the Oxford Botanic Garden, and the great cedar tree there near Daubeny's laboratory was most probably planted at about the same time. The story about the transport of the little seedling in Jussieu's hat, or as the French call it *le fameux cèdre-bébé de Syrie*, is very charming; but it is a fairy tale.

# RESEARCH ITEMS

### Metabolic Stimulants and Wound Healing

T. H. C. Barclay, D. P. Cuthbertson and A. Isaacs (*Quart. J. Exp. Physiol.*, **32**, 309; 1944) measured the time required for healing standard circular skin wounds in rats. In normal animals the time was about 20 days. Addition of dried thyroid gland to the diet throughout the healing period reduced the average healing time by 11 per cent. Addition of 2-4-$\alpha$-dinitrophenol (0·012 per cent of diet) reduced the healing time by 15–27 per cent. Larger doses of dinitrophenol (0·09 per cent of diet) were without effect, possibly because of the great loss of weight which occurs. The results were shown to be statistically significant; but the authors do not think that they justify the use of these stimulants to aid wound healing in patients. It has been shown by others that these substances have no effect on the rate of cell proliferation *in vitro*, and it is suggested that the *in vivo* effect may be due either to increased circulation-rate improving the blood supply to the wound, or to cell proliferation induced by some product of the increased body catabolism.

### Posterior Pituitary Extract and the Heart-Rate

THE slowing of the heart which results from injection of posterior pituitary extract has been ascribed to (1) reflex slowing from the rise of blood pressure, and (2) depression of the myocardium either directly or as a consequence of coronary vasoconstriction. M. E. M. Sawyer and G. H. Ettinger (*Canad. J. Res.*, **22**, E, 26; 1944) claim to have shown that neither of these factors is responsible. The experiments were performed on conscious dogs; the extract was administered by continuous intravenous infusion over a period of one to two hours at the rate of about 2 pressor units per hour. In normal dogs the heart slowed to about half its resting rate. Dogs whose hearts had been completely denervated (by a preliminary operation) showed no slowing at all; this confirms earlier work of Z. M. Bacq and S. Dworkin (*Amer. J. Physiol.*, **95**, 605; 1930) and proves that the slowing is mediated by the nervous system and is not due to any direct action of posterior pituitary on the heart. It would seem likely that the slowing is a reflex effect from the rise of blood pressure; but the authors present the following evidence against this view. In one dog the blood pressure actually fell by 5 mm. mercury, yet the heart slowed from 72 to 52 beats per minute. In the remaining six dogs the rise of pressure was small (10–30 mm. mercury) and the slowing was maintained for some time after the pressure had returned to normal. Such evidence is suggestive; but much more will be required before the effects of blood pressure changes can be ruled out.

### Cultivation of *Plasmodium gallinaceum* in Tissue Cultures

No one, says F. Hawking (*The Lancet*, 693; May 27, 1944), has yet succeeded in cultivating the trophozoites of malaria parasites *in vitro* for an indefinite period; but he has now succeeded in cultivating *Plasmodium gallinaceum* of birds in roller-tube tissue cultures of tissue from the spleen, liver, marrow and brain. It will be remembered that S. P. James and P. Tate (*Parasit.*, **30**, 128; 1938) showed that this and certain other avian plasmodia show stages which develop in reticulo-endothelial cells and in the capillary endothelium of the brain and other organs (the exo-erythrocytic forms). The occurrence of similar stages in the life-history of the human malaria parasite has not yet been proved. The commonest form of the parasite found by Hawking in his tissue cultures was the large oval schizont, which was usually found free from any cell. Small mononuclear forms were also fairly common. At the time of writing, Hawking had found apparently healthy parasites on the fifteenth day of culture, after which time the cultures were overgrown by fibroblasts. Tissue taken from tubes on the eighth day and injected intraperitoneally into chicks infected these with typical endo- and exo-erythrocytic forms. Fluid taken from several tubes on the ninth day and injected intraperitoneally into chicks infected them. Hawking thinks that multiplication of the parasites really occurs in the cultures, because, although parasites are hard to find in the original implant, they are present in large numbers after several days of cultivation, and clusters of tiny mononuclear forms are often found (which are figured), and these may be the results of schizogony. A detailed description of the forms of the parasites seen during this work will be published later.

### Venezuelan Catfishes

LEONARD P. SCHULTZ studied and collected the fishes in the Maracaibo Basin of Venezuela and other localities in the winter of 1942, and now makes a detailed report on some of them ("The Catfishes of Venezuela, with Descriptions of Thirty-eight New Forms", *Proc. U.S. Nat. Mus.*, **94**, No. 3172; 1944). 127 species and subspecies and 63 genera are recognized in this work—38 new forms are described and 6 new genera. Keys are given of the families, genera and species, and the whole will be a most useful help to all ichthyologists. The chief value lies in the fact that nearly all the material was collected personally and that colour notes were made from the live fishes. The common names are frequently included, and in several cases the young are compared with the adult.

### Asymmetry in Inheritance

G. DAHLBERG (*Proc. Roy. Soc. Edin.*, **62**, 20; 1943) has considered the question of asymmetry of pattern or of expression of such characters as polydactyly. Frequently such a character appears on one side in one individual and on both sides in another individual. Suggestions have been made that both environment and genes are the causative agents of this phenomenon. The author, however, indicated that manifold genotypical asymmetry, due to genic influence, will account for the apparently erratic behaviour. The final effects may arise from a gene or several genes acting at a particular stage in development where planes of symmetry are being formed. The genes may act by determining the distribution of extra-nuclear factors. This genotypic asymmetry entails a distinct form of latency to be distinguished from latency due to Mendelian recessives and from environmental thresholds. The author indicates suitable subjects for tests of the theory.

### Petrogenesis of the Transkei Dykes

NORTH of East London in the Cape Province of South Africa there are two immense dykes which, appearing near Cathcart, follow an easterly direction for nearly a hundred miles before they are cut off by the coast, where each of them has a thickness of about 1,000 ft. The various types of rocks which make up the dykes have been interpreted as differentiation products due to the fractional crystalliza-

tion of a dolerite magma (F. Walker, *Trans. Roy. Soc. S.A.*, **30**, 79; 1943); but a more detailed investigation has led E. D. Mountain to a very different conclusion (*Trans. Geol. Soc. S.A.*, **46**, 55; 1944). The main dyke-rock is a dolerite-pegmatite which differs chemically from the normal Karroo dolerite in containing higher potash and combined water, and lower magnesia. Patches of rock with the same characters have been produced in normal dolerite as a result of contamination by sediments, and Prof. Mountain presents evidence that the dolerite-pegmatite was formed by large-scale contamination of the same kind. As it is traced to the west, the southern dyke passes imperceptibly into normal Karroo dolerite. The northern dyke, however, becomes increasingly acid towards the west and finally becomes a quartz-felspar rock indistinguishable from a metamorphosed sediment. Along one stretch the northern dyke encloses a 20-ft. dyke-like band of essentially sedimentary material which can be matched with the neighbouring Beaufort sandstone. This 'dyke' persists for several miles; but eventually it grades into granophyric quartzite, which in turn merges continuously through granophyric dolerite into dolerite pegmatite. The rock sequence from dolerite to sediment is identical with that commonly observed in the reaction rims around sedimentary xenoliths found in dolerite.

### Solubilization by Soap Solutions

THE name 'solubilization' is applied to the power possessed by even dilute water solutions of soaps (and other colloidal electrolytes) of bringing into thermodynamically stable colloidal solution such substances insoluble in water as hydrocarbons and dyes. The commercial importance of this phenomenon has long been known; but its mechanism has only recently been given by J. W. McBain as consisting of sorption upon, or incorporation within, colloidal micelles. J. W. McBain and K. E. Johnson (*J. Amer. Chem. Soc.*, **66**, 9; 1944) have now shown by measurements with a water-insoluble dye and four potassium soaps that the solubilization increases so rapidly with the higher soaps as to cast doubt on the suggestion that it is solution in the hydrocarbon fraction of the molecule; but rather favour its incorporation between the layers of lamellar micelles, the only form for which there is direct evidence. Potassium chloride greatly increases the solubilizing power of fully formed micelles and also produces in dilute solution micelles of still higher solubilizing power.

### Structure of Boron Carbide

THE very hard boron carbide, $B_4C$, has been examined by the X-ray method by Zhdanov and Sevast'yanov (*C.R. Acad. Sci. U.R.S.S.*, **32**, 432; 1941—in English) and by H. K. Clark and J. L. Hoard (*J. Amer. Chem. Soc.*, **65**, 2115; 1943), whose results are in agreement. The structure is very unusual, the type of co-ordination shown by the boron and carbon being curious. $B_4C$ belongs to a rhombohedral lattice, with constants $a = 5{\cdot}19$ A. and $\alpha = 66° 18'$, with three stoichiometric molecules $B_4C$ in the unit cell. The corresponding hexagonal lattice constants are $a = 5{\cdot}60$ A. and $c = 12{\cdot}12$ A. for a cell containing nine molecules. The structural units are a linear chain of three carbon atoms and a group of twelve boron atoms arranged at the vertices of a nearly regular icosahedron. Each boron has six-fold co-ordination, being bonded to five others in the same icosahedral group and to either a carbon or a boron. Thus a continuous three-dimensional network of boron runs through the crystal. A high degree of resonance leading to a condition not far removed from metallic binding is presumably of considerable importance in accounting for the stability of the structure, and the boron network is not of the ordinary covalent type.

### Squirrel-Cage Induction-Motor Starters

A PAPER by G. A. Wauchope (*J. Inst. Elec. Eng.*, **91**, Pt. 2, No. 20; April 1944) describes a recent development in this class of apparatus. In a pumping station in which were installed a number of pumping units automatically started and stopped by changes in water-level, the motors were of the 3-phase double-wound squirrel-cage-rotor type controlled by contactor-type star-delta starters. During the starting period, the current was found to be higher than anticipated, with the result that the starter overload releases had to be provided with special restraining devices to prevent tripping under normal starting conditions. It was further observed that the high current-peak occurred when the motor connexions were automatically changed from star to delta. This phenomenon occurred in installations where the motors were of the simple squirrel-cage type as well as where the rotors were of special design to limit the starting current. The author gives reasons for the occurrence of the phenomenon and describes a new design of star-delta starter for squirrel-cage motors which followed from the investigation. The starter enables squirrel-cage machines to be used in many fields where a slip-ring motor has formerly been essential.

### Invariants and Tensors

THE theory of invariants was much studied, particularly by Cayley, Sylvester and Clebsch, in the second half of the nineteenth century. Its central problem was, given an equation representing some geometric configuration, to find functions of the coefficients of that equation which were unchanged in form when the axes of reference were altered. In the twentieth century the theory of relativity brought into great prominence the use of tensors; these can be used for expressing physical laws which are independent of the axes of reference. These two theories have now been linked up together in an important paper by D. E. Littlewood (*Phil. Trans.*, A, **239**, 305; 1944). He proves that all the results of the older theory can be obtained in the new. Moreover, there is a close correspondence between the symbolic method for invariants, introduced by Aronhold and developed by Gordan, Grace and A. Young, and the tensor method. The chief difficulty in both cases is that, although it is easy to write down an unlimited number of expressions which have invariant properties, it is difficult to decide whether any one of these may not turn out to be identically zero, or whether any two of these may not represent the same invariant. To do this requires a somewhat elaborate technique. That for the symbolic method is based on ordinary algebra, but the corresponding technique for tensors is more akin to group theory, and in particular to the quantitative substitutional analysis of A. Young. It is remarkable that Young developed this, not from tensors, but from his work on the symbolic method. Littlewood's paper appears to open up several promising lines of investigation, some of which will be discussed by the author in a later paper.

# STIMULATION OF THE ANTERIOR HYPOPHYSIS BY ŒSTROGENIC HORMONE

By PROF. BERNHARD ZONDEK
Hebrew University, Jerusalem

RECENTLY, we have reported a series of findings showing partial blockage of the anterior hypophysis in rat and fowl by prolonged treatment with œstrogenic hormone[1,2]. In these experiments it proved possible to eliminate growth hormone and gonadotrophic hormone by treatment with œstrogens, and as a result eunuchoid dwarf rats and similarly impaired chickens could be produced. Growth was found to be inhibited by the treatment to 60 per cent in the rat and to 30 per cent in the fowl. Inhibition was marked when large doses of œstrogens were given for a longer period.

Stimulation of anterior hypophysis by œstrogenic hormone is less certainly established experimentally than is the inhibition of this gland by œstrogens. The starting point of the present investigation was the hypothesis that the degree of stimulation of the anterior hypophysis by œstrogens depends on the manner in which the hormone is administered. Continuous administration of hormone to the organism is best achieved by the implantation of hormone pellets as suggested by Deanesly and Parkes[3]. The daily resorption rate in this form of administration amounts to 1–5 per cent.

In our experiments we implanted 10 mgm. pellets of œstrone* in the uterine cavity of fifteen infantile rabbits. Ten of the rabbits succumbed from secondary peritonitis in the first month after implantation due to necrosis of the uteri as a consequence of continuous treatment with œstrogens[4].

*Giant Growth:* One rabbit 16 months after the implantation exhibited an extraordinary group of changes: namely, well-proportioned giant growth, the body weight attaining 3,900 gm., as against only 2,900 gm. in the control; enormously swollen breast glands, milk production equal to that usual in a lactating rabbit after parturition, and ovaries weighing 1·1 gm. (as against 0·2 gm. in the control) consisting of a solid mass of lutein tissue entirely free from primordial or mature follicles. Enormous alterations were also found in the other sexual organs, but could be attributed to local and direct effects of the implanted œstrogen. Thus, particularly large, benign tumour-like polyps were found at the portio uteri; excessive proliferation with polyp formation was noted in the vagina and uterine mucosa; and degenerative changes of a type already described[4], especially hyperæmia, bleeding and infarct-like necrosis of the myometrium, were detected in the uterus. Summarizing, it was possible to suggest that continual stimulation of the anterior pituitary with œstrone is able to induce hypersecretion of growth hormone, gonadotrophic hormone (luteinizing factor), and lactogenic hormone. Regular daily resorption of about 0·018 mgm. (= 180 I.U.) of œstrogen was necessary to obtain this effect.

A considerable obstacle to experimentation on stimulation of the anterior hypophysis by œstrone is the difficulty of inducing a regular resorption of tested œstrogen in optimum dosage. We attempted to reproduce our earlier results in two further series of implantation tests, but were able to elicit slight symptoms of somatotrophic, gonadotrophic and mammotrophic stimulation only in two out of thirty female rabbits implanted with œstrone. It seems that œstrogen resorption in optimum dosage is attained but seldom, and it is possible that the ideal œstrogen for stimulation would be one which is resorbed very slowly and gradually.

*Thyrotoxicosis:* In earlier experiments[5] on impairment by protracted œstrone treatment of anterior pituitary function in rats, three out of a hundred rats treated by us with 5,000–20,000 I.U. of œstradiol benzoate in twice-weekly subcutaneous injections gave a singular reaction. The three were females which had received respectively $2 \times 5,000$, $2 \times 10,000$, $2 \times 20,000$ I.U. of œstradiol benzoate weekly. In these individuals, seven months of œstrone treatment had elicited, not stunting of growth but typical symptoms of gonadotrophic and somatotrophic inhibition, and in addition clear-cut symptoms of Graves' disease, including a slight exophthalmos. The pronounced general body tremor induced in these animals by touch proved symptomatic of a state of extreme excitement and nervousness which was combined with diarrhœa and alopecia. The basal metabolic rate of the animals was found, in fact, to be 20 per cent higher than in untreated controls of the same weight or age, and than in other œstrogen-treated rats of the same experiment. The thyroid glands at death were not in a stimulated condition, which was in accordance with the clinical picture of the animals before death, the thyrotoxic symptoms having disappeared. It seemed from these results that symptoms of Graves' disease (increased basal metabolic rate, nervous excitement, tremor, diarrhœa, alopecia) and exophthalmos in female rats might be produced by constant œstrogen stimulation. It was found impossible, however, to produce such an effect regularly.

In another series of experiments, thirty female rabbits, weighing 1,000 gm. each, were used and in each was implanted in the peritoneal cavity (between uterus and rectum) a pellet of œstrone weighing 10 mgm. Since earlier experiments had indicated that about two thirds of the animals subjected to this treatment are liable to early death from local injury to the uterus, both uterine horns of all animals used in the present investigation were extirpated at implantation. The animals were kept in cages in groups of two, one control together with one implanted specimen. The diet was composed of beetroot, carrots, wheat, bran and cabbage.

One of the thirty rabbits developed striking symptoms of hyperthyroidism within four months after the implantation. An unambiguous exophthalmos, which became aggravated when the animal was excited by removal from its box, was developed. In addition, other thyrotoxic symptoms such as diarrhœa, loss of hair, nervous excitement, acceleration of breathing and of pulse-rate and loss of weight (implanted animal 1,150 gm., control animal 2,900 gm.) were evident. The animal, which normally would have more than doubled its weight, suffered entire loss of its fat pads. Progredient cachexia gave it an appearance of little more than skin and bones.

In a metabolism cage, the daily food intake of the thyrotoxic specimen was 760 gm., as compared with 920 gm. in a control rabbit of the same weight. The urine of the thyrotoxic rabbit contained 0·4 mgm. per cent urea in an average daily volume of 110 c.c.

* We are indebted to Dr. B. J. Brent, Roche-Organon Inc., Nutley, N.J., for his kindness in supplying œstrone.

Urine of a young normal rabbit of the same weight (1,150 gm.) contained 0·1 mgm. per cent in an average daily volume of 200 c.c. The thyrotoxic rabbit, therefore, excreted about 100 per cent more urea daily than a normal rabbit of the same weight.

Assay of the thyrotrophic hormone content of samples of blood and urine from the thyrotoxic rabbit by injection into guinea pigs did not indicate presence of an abnormally high amount of thyrotrophin.

The basal metabolic rate of the thyrotoxic rabbit, as compared with that of normal controls of the same weight, and of untreated controls of the same age but double the weight (2,900 gm.) was quite distinctive. The carbon dioxide production in the thyrotoxic animal averaged 1·2 gm., as against 0·9 gm. in the weight control, and 0·8 gm. in the age control. This means an increased basal metabolic rate of 30 per cent compared with the weight control, and of 50 per cent compared with the age control.

An electrocardiogram of the exophthalmic rabbit had the following features: normal sinus rhythm; frequency 292; *P*-waves invisible in lead I and sharp and high in leads II and III; voltage high in lead I, especially high in leads II and III (1·1 and 1·2 MV. respectively); *T*-waves flat in lead I; normally positive in leads II and III. Summary: tachycardia, high *P*-waves, and high voltage, changes similar to those found in Graves' disease in man.

The exophthalmos, first noted four months after the implantation of the 10 mgm. œstrone pellet, persisted for four months, then gradually decreased, vanishing finally at a term which probably followed closely on the completion of the resorption of the implanted hormone depot. During this period, the basal metabolic rate of the formerly thyrotoxic rabbit reverted to normal (0·9 gm.) and before death even became subnormal (0·78 gm. carbon dioxide per hour per kgm. rabbit). The subnormal phase did not persist, however, for very long, since the animal died suddenly of emaciation a month after the disappearance of the exophthalmos, that is, five months after the appearance of exophthalmos, and nine months after implantation of the œstrone pellet, the animal at death being about a year old. Repeated ophthalmologic examinations of the fundus throughout the entire course of the experiment failed to reveal any pathological change.

The thyroid gland of the experimental animal exhibited no remarkable macroscopic or microscopic change. This finding was to be expected, since the animal died a month after the disappearance of the thyrotoxic symptoms, and after the basal metabolic rate had returned to normal values. The orbita showed no residue of exophthalmic œdema.

Creatin and creatinin assays of the urine carried out on the animal during the last months of its life yielded a puzzling result: only traces of creatin and creatinin were detected, whereas controls showed normal values of total creatinin (60 mgm. per cent) and traces of creatin. The absence of creatin(in) in the urine of the test animal in the post-thyrotoxic period may be explained possibly as the result of a retention of protein-building substance by the body for purposes of regeneration.

The œstrone pellet implanted into the peritoneum at the commencement of the experiment was sought at autopsy but had been entirely resorbed. This finding accorded well with the observed disappearance of all symptoms of thyrotrophic stimulation one month before the death of the rabbit. On the assumption that resorption of the 10 mgm. œstrone pellet was complete eight months after implantation, the rate of resorption was approximately 0·04 mgm. (= 400 I.U.) per day.

While it has been demonstrated in earlier experiments that protracted treatment with large doses of œstrogens blocks part of the functions of the pituitary anterior lobe, the above experiments show that it is possible also to stimulate the anterior lobe by œstrogens. Appropriate dosage and steady resorption of the œstrogenic hormone seem to be of importance for the induction of the stimulating effect. For this reason experiments designed to stimulate the pituitary gland do not succeed regularly.

The investigation reported here was generously aided by a donation from the Ella Sachs Plotz Foundation.

# THE SCIENTIFIC OUTLOOK AND ITS PRESENTATION BY FILMS

By GEOFFREY BELL

THE new tools produced by men of science, particularly the instruments of mass communication, have placed the peoples of the world in a new environment. Characteristics of this are an immensely increased freedom of movement in space for every individual, and also an emphasis upon technology as a directive of social endeavour. We are having to adapt ourselves accordingly. Everyone now needs some knowledge of science, and a feeling for the scientific outlook if he is to live happily in this new environment. What means has the man of science to hand for presenting the scientific way of life so that it can become a habit of thought with the average person?

A quarter-century ago, Dr. Comandon, a biologist, wrote: "In our days, motion pictures are a necessity to the scholar who wishes to demonstrate to his colleagues transitory phenomena, delineate experiments or the general observation of things, beings or facts. . . . Some of these films, properly arranged, have proved useful for documentation, teaching and scientific propaganda."[1] These ideas have not been without fruit.

Before dealing with the broad problem, reference must be made to the use, mentioned here, of the film as a tool for scientific workers themselves. Science is no longer thought of as a regime of study and inquiry within watertight compartments of knowledge; it has come to realize that it must 'know itself'. At a meeting of the Association for Scientific Photography, Prof. Yule Bogue said: "Any particular branch of industry or science is largely dependent for its own advancement upon progress made in other branches. In order that the maximum benefits may accrue it is essential that knowledge of these advancements be disseminated as widely as possible."[2] It is the purpose of the Association for Scientific Photography to foster this use of the scientific film (as

well as the still photograph), as pleaded by Dr. Comandon twenty-five years ago. The cinema of to-day is itself an interesting example of the integration of departments of science, bearing fruit through this kind of synthesis. Its lenses, lighting apparatus, thermionic valves, photo-electric cells, and the acoustic design of its film studios and cinemas, all have their genesis in different branches of physics; while its photographic emulsion is a product of chemistry.

To what extent is the film being used for 'scientific propaganda', the fostering of that integration of science with society, which the man of science should demand of this, one of his own creations?

There is one direction of progress with which most people are familiar—the documentary and the instructional film. Documentary technique has been described as the "creative interpretation of reality". The more straightforward, less 'interpretive', treatment of reality produces the instructional or educational film. Part of the reality, which which the documentary film makers deal, is necessarily the relations between science and society. The film "Night Mail", for example, translated a technological achievement, the regular running of the Scottish night mail train, into an inspiring social document. "Song of Ceylon", an impressionistic documentary of life in Ceylon, had as part of its theme the impact of Western civilization (which includes technology) upon this Oriental culture. "Men of Africa", using a different, more factual technique, tells the same sort of story for part of Africa. These are three well-known documentary films. Yet none of them was set out primarily as 'scientific propaganda', though, in a large measure, that is what they are.

On another side the documentary film makers have courted science. Large commercial interests—notably gas and oil—were concerned with applied science, as well as sales promotion. They took the view that the best form of advertising was to inform the public about the techniques they used. Both interests made good expositional films dealing with aspects of their work, such as "How Gas is Made", "Oil from the Earth", "Lubrication of the Petrol Engine". They also made films with a wider emphasis, such as "Enough to Eat" (British Commercial Gas Association) and "Malaria" (Shell). Gas is used for cooking food, hence the interest of food problems to users of gas; oil is used for killing mosquito larvæ, hence the interest of malaria to oil users. Both films have a social value which soon becomes generally known—particularly if their approach is free from advertisement or bias, and has integrity. Hence their value from a public relations point of view. (It is worth noting, for example, that "Malaria", though made by an oil company, describes the use of Paris green as a means of killing mosquito larvæ alternative to the usual oil film.) The G.P.O. Film Unit (now Crown Film Unit) also produced such excellent expositional films as "How the Telephone Works", as well as the more 'human' documentary. Latterly, the chemical industry has produced a series of detailed instructional films on anæsthetics, and a long documentary—"The Harvest Shall Come"—which deals with the social and economic problems of the agricultural worker. The connexion of the chemical industry with medicine and agriculture is left to be assumed from the content, rather than explicitly stated in these films.

Such films are widely seen by audiences outside the public cinema. They are shown by clubs, institutes and film societies. Many are used in schools and technical colleges for direct teaching and for general educational purposes. The Services have been using them during the War. The War, in fact, has brought about an important development in this field; the Ministry of Information has become the central agency for Government film production. Besides films of general informative value, it has made films on civil defence, aspects of public health and of agriculture. They are available through the Central Film Library, which distributes them free to anybody wishing to show them. Most of them give the lay public a good elementary education in the applications of science with which they deal.

Besides these there is the 'popular science' type of film, best known of which is the Gaumont-British "Secrets of Nature" series. They were often produced in two versions—one for schools, and one with a 'popular' commentary for the cinemas. They were basically instructional films, pointing at scenes and facts rather than interpreting them in a wider setting.

All such films, particularly those obtainable from free libraries, were a potential source of supply for a new kind of audience—the scientific film society. In 1938 there were two of these—in London and Aberdeen. Then the War seemed to act as a stimulant. In 1941 there were six societies in Scotland[3], and in 1942 the Scientific Films Committee of the Association of Scientific Workers called a Scientific Films Conference, when it became clear that more societies would soon form. To-day there are in the British Isles some fifty scientific film societies. They are generally open to anyone who wishes to join, for an annual subscription of a few shillings; some half-dozen shows, of about two hours each, are given during the winter months, commonly at week-ends.

The interest of these societies is now brought to a focus by the Scientific Film Association[4], the present address of which is c/o Royal Photographic Society, 16 Princes Gate, London, S.W.7. The broad purpose of the Association is to develop the film medium in every way, to further the integration of science and society. It believes that the 'man in the street' must become the 'citizen-scientist'. The scientific film society which shows films to its members helps, in one way, to bring this about. For each such society forms an audience, at once appreciative and critical, which is a potential encouragement and guide to the makers of scientific films. Small and economically unimportant though it may seem, each such society is a growing point fostering the scientific outlook, and the Association encourages the formation of as many of them as possible.

The following things, among many, are needed: the development of a system of viewing, grading and appraising scientific films; a panel to advise film producers on scientific matters, and to check the accuracy of technical detail; technical assistance to scientific men and others working on scientific films; a free, central, scientific film library; and more scientific films in the public cinemas.

Most of these are long-term matters, though a beginning can be made now; a system of viewing and grading, for example, is being developed. But such things as the distribution of scientific films in public cinemas will take longer to achieve. This brings us to wider fields, outside the range of the physics and chemistry which produced the sound film. For the film has a unique power of conjuring into something very like reality a world which hitherto belonged only to the minds of men.

This has a special reference to the problem stated above—that social progress demands the integration of science and society. When this statement is made to the ordinary person, he has difficulty in even seeing its meaning. But in a film we can show him, let us say, a bare spot on a bacteria culture, where a Penicillium spore has fallen. We can show it to him through a microscope, and abstract ideas connected with it can be presented by a moving diagram; the scientific man's own deductions from this scene can be made 'real' by sound. The concept 'science' becomes something he can understand—in this case it may say "penicillin is bacteriostatic". The same film can also show wounded men being brought back from the coast of France and rejoining their families. The concept 'society' becomes also a real thing—ordinary people and their lives. The film can arrange its strips of celluloid so that the sounds and the pictures of these representations are linked together; science and society are shown to be integrated. The film brings to 'reality' something that is otherwise but a mind picture, inaccessible to many. Its audiences gradually become 'citizen-scientists' in the sense that they grow to appreciate that science is part of their lives.

But the film medium, like all scientific tools, is powerful for ill as well as good. It does not necessarily tell the truth—indeed there are certain fundamental difficulties in the way of its doing so. The viewing and appraising of films which deal with science is therefore an important task. The lives of such scientific workers as Pasteur, Ehrlich, Faraday and Curie have been put upon the screen, and in very different ways. Most recently, psycho-analysis has received the attentions of Hollywood. Some of these films are good in their effect; others are bad. Since the public will get much of its ideas of scientific workers and of scientific method from the cinema, it is vital that those ideas should be soundly inspired. It is more than a matter of physics and chemistry.

[1] From "The Film in National Life", published 1932 by the Commission on Educational and Cultural Films. The Commission was originally brought into being through the agencies of the British Institute of Adult Education and the Association of Scientific Workers. It resulted in the formation of the British Film Institute.

## THE MAXWELL LABORATORY AT THE UNIVERSITY OF MOSCOW

By PROF. V. ARKADIEV

THE Maxwell Laboratory of Electromagnetism in the Physics Department of the Moscow State University was inaugurated twenty-five years ago, and this anniversary has been commemorated recently.

The work carried on in this Laboratory has dealt mainly with Maxwell's electromagnetic theory of light, with the view of the further development of its fundamental principles: (1) light as an electromagnetic phenomenon; (2) the optical properties of bodies (such as lustre, transparency, refraction of rays, etc.) can be computed in advance according to their electrical and magnetic properties. The laboratory work has established further the identity of light with electromagnetic waves and the analogy existing between the two latter aspects of waves. In 1922 the Laboratory discovered a new source of radiation, the mass-radiator; this enables one to obtain intermediate ultra-Herzian waves, which form a connecting link between radio- and heat-waves. In 1934 special plates, sensitive to Herzian waves, were invented and prepared in the Laboratory; these plates have made possible the application in radio engineering of methods employed in photography (stictography), namely, those of fixing the traces left by radio waves upon paper.

Shortly before the War, the Laboratory demonstrated the possibility of using radio waves for radioscopy and suggested special screens, luminescent under the action of centimetre waves, similar to those used for X-rays. In the course of the further development of Maxwell's theory, the Laboratory has elaborated a comprehensive theory of 'passive' spectra, the most interesting result of this theory being the application of spectral analysis to the study of the magnetism of bodies; this involves the application of methods of mathematical analysis of optical absorption spectra to the investigation of the process of magnetization, particularly of the magnetization of technical magnetic materials.

The theory of passive spectra has been applied to the behaviour of matter of every description, beginning with the ionosphere and gases and ending with its coarser aspects, such as resin, cast iron, ores and rocks.

The combination of Maxwell's electromagnetic equations with the laws of motion established by Newton affords the possibility of obtaining general equations, representing a scheme of the behaviour of matter along the entire scale of electromagnetic waves. Among other things the scheme enables us to deduce the dispersion of Debye's dielectrics, the magnetic dispersion of paramagnetics and Compton's formula for the refraction coefficient for X-rays. An analogous inference is obtained for the magnetic properties of ferromagnetic bodies in the region of the ultra-Herzian waves, where the magnetic spectrum of ferromagnetic bodies is transferred into its own 'Röntgen' region in which, owing to the high frequency of the vibrations, only insignificant vestiges of the magnetic properties can remain.

## AXIS ORIENTATION OF QUARTZ CRYSTALS

AN article by G. W. Willard (*Bell Lab. Rec.*, 22, No. 7; March 1944) deals with the methods used in inspecting quartz crystals and in determining the axis orientation. In the original crystallization of quartz, foreign substances, such as other minerals or bubbles of gas or liquid, may be included, and part of the inspection procedure is undertaken to locate such inclusions so that they may be cut away. One of the dangers of using plates with inclusions is that the resulting discontinuities in their elastic and thermal properties may cause them to crack under the influence of temperature changes. Another common defect is the presence of cracks, due either to the effect of inclusions or to the rough treatment the quartz receives in river beds or in being broken from its natural formation. These cracks may be completely internal and very fine, and thus not

apparent on casual inspection. Another common defect arises from small interior bubbles. These may be isolated or grouped irregularly, or in very fine form may exist in lines or in plane or curved sheets, when they are called needles, phantom planes, or veils. So common are defects in quartz that only one in a hundred of the mined stones is saved for piezo-electric use.

Besides these various physical defects, crystals as found may have two other types of defects that result from structural misgrowth of otherwise perfect crystals, and give no evidence of their presence during inspection in ordinary light. The two types of quartz crystals, right-hand and left-hand crystals, can both be used in electrical work, but a single plate should not include material of both types. Although twinning, or the presence of both types in the same crystal, is common, usually any one crystal is predominantly of one type. A region containing twinning usually consists of thin layers of opposite kind. Inspection for optical twinning consists primarily in locating these small regions of unusable material so that they may be discarded in cutting.

The other form of twinning that may be present is electrical twinning. With such twinning, adjacent regions of quartz have their electric axes of opposite poles. This form of twinning is also common, but it differs from the optical in that each type may occupy large regions of the same crystal. Either type is usable, but not both in the same plate. During inspection the dividing line between regions of different types is marked on the crystal, so that eventually the regions may be separated and each section cut properly with respect to its own electric axis. The article illustrates photographically various kinds of crystal faults and describes the laboratory apparatus and procedure employed in examining the crystals.

# FORTHCOMING EVENTS

## Tuesday, August 8

QUEKETT MICROSCOPICAL CLUB (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Exhibition of Specimens, and Discussion.

# APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT LECTURER IN THE DEPARTMENT OF MATHEMATICS, an ASSISTANT LECTURER (temporary) IN THE DEPARTMENT OF PHYSICS, and an ASSISTANT LECTURER (temporary) IN THE DEPARTMENT OF ENGINEERING (with special qualifications in Electrical Engineering)—The Registrar, University College, Singleton Park, Swansea (August 5).

LECTURER IN MECHANICAL ENGINEERING in the Denbighshire Technical College—The Director of Education, Education Offices, Ruthin, Denbighshire (August 5).

LECTURER (woman) IN MATHEMATICS in the Bingley Training College—The Education Officer, County Hall, Wakefield, Yorks. (August 7).

ASSISTANT LECTURER IN MECHANICAL ENGINEERING, an ASSISTANT LECTURER IN ELECTRICAL ENGINEERING, and an ASSISTANT LECTURER IN MINING, in the Cannock Chase Mining College—The Director of Education, County Education Offices, Stafford (August 8).

SENIOR TECHNICAL OFFICER (temporary) at London Headquarters of the Ministry of Town and Country Planning—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. EA.950A) (August 10).

ASSISTANT EDUCATIONAL PSYCHOLOGISTS (2)—City Education Officer, 12 St. Giles Street, Edinburgh 1 (August 11).

ASSISTANT MASTER (Graduate) to teach MATHEMATICS in the Sheffield Junior Technical School—The Director of Education, Education Office, Leopold Street, Sheffield 1 (August 12).

TECHNICAL OFFICER—The Executive Officer, Holland War Agricultural Executive Committee, 15 Market Place, Boston, Lincs. (August 12).

ASSISTANT LECTURER IN METALLURGY—The Registrar, The University, Leeds 2 (August 19).

READERSHIP IN PHYSICAL ANTHROPOLOGY—The Registrar, University Registry, Oxford (August 31).

CHAIR OF ELECTRICAL ENGINEERING—The Acting Registrar, The University, Leeds 2 (September 30).

LIBRARIAN—The Librarian, Queen's University, Belfast (October 31).

LECTURER IN THE SCIENCE DEPARTMENT (principal subjects: Inorganic, Organic and Physical Chemistry, with subsidiary Physics)
—The Registrar, Merchant Venturers' Technical College, Bristol.

CHAIRS OF PATHOLOGY, PHYSIOLOGY and SURGERY in the Royal Faculty of Medicine, Baghdad, Iraq—The British Council, 3 Hanover Street, London, W.1.

SENIOR TECHNICAL OFFICER—The Secretary, Warwickshire War Agricultural Executive Committee, 8 Guy's Cliffe Avenue, Leamington Spa.

SPEECH THERAPIST—The Director of Education, Education Office, Chapel Street, Salford 3.

SCIENCE MASTERS (2), one PHYSICS and one CHEMISTRY, at Victoria College, Alexandria—The British Council, 3 Hanover Street, London, W.1 (endorsed 'Alexandria').

# REPORTS and other PUBLICATIONS

*(not included in the monthly Books Supplement)*

## Great Britain and Ireland

Scientific Proceedings of the Royal Dublin Society. Vol. 23 (N.S.),
No. 24: Studies in Peat, Part 11: Peat-Tar Oils. By J. Reilly, Patrick
Moynihan and Desmond Reilly. Pp. 239–246. 1*s*. Vol. 23 (N.S.),
No. 25: Studies in Peat, Part 12: Mona Wax (Irish Peat Wax) and
Emulsification. By J. C. Aherne and J. Reilly. Pp. 247–256+plate
10. 1*s*. 6*d*. (Dublin: Hodges, Figgis and Co., Ltd.; London: Williams [47
and Norgate, Ltd.)

Report on the Extension of Scientific Research in Manchester
University particularly in relation to the Industries of its Area. Pp. [47
27. (Manchester: Manchester University Press.) 1*s*. net.

Agrarian Problems from the Baltic to the Aegean: Discussion of a
Peasant Problem. (Post-War Problems.) Pp. 96. (London and New [57
York: Royal Institute of International Affairs.) 3*s*. net.

Imperial Agricultural Bureaux. Joint Publication No. 7: Imperata
Cylindrica; Taxonomy, Distribution, Economic Significance and
Control. Pp. 64. (Aberystwyth: Imperial Agricultural Bureaux.) [57

# WATER POLICY IN GREAT BRITAIN

PUBLIC interest and concern regarding water-supply, expressed in Parliament, in the Press and in the debates of various professional bodies, has never been so general, or so generally well informed, as it is to-day. Interest increases primarily because of almost chronic threats of shortage, which only the foresight of water engineers has usually prevented from becoming actual. The threats themselves occur because the ever-growing demand outstrips provision. Growth of population in 'new' centres is an obvious problem ; but in general it is of far less importance than the rise in standards of living. Populations which were satisfied fifty years ago with a daily supply of ten or fifteen gallons a head are now barely served with thirty. Even less generally appreciated is the ever-growing demand of industry. The concern increasingly felt has been stimulated by a recent succession of serious droughts. Finally, the feeling that something is wrong has almost certainly been brought to a climax by the war-time experience that demands can be met 'when the devil drives'. The stupendous requirements of camps, aerodromes and factories have been surprisingly fulfilled, mainly by resort to underground water.

The foregoing circumstances explain the recent production of the White Paper on "A National Water Policy" (Cmd. 6515. London: H.M. Stationery Office), and the joint debate in April, arranged by the Geological Society and the Institution of Water Engineers, on "Water in Relation to Town and Country Planning". Some of the main points raised during this meeting are presented elsewhere in this issue (p. 171), and a fuller account has been published by the Geological Society. Shortly before the meeting was held, the Institution of Water Engineers had issued a statement on "Post-War Water Supply", and the Labour Party a pamphlet on "Post-War Water Policy". All who read and compare these various documents must be struck by the great measure of agreement regarding the nature of the problem, and the lines along which its solution must be sought. Behind the growth of this unanimous and informed opinion lies the slowly maturing efforts of water engineers and geologists over a period of many years.

The initiation in 1924 of regional advisory water committees, assisted by the Ministry of Health, was one of the earliest developments in water-supply planning. Slightly earlier, the Ministry had instituted its own Advisory Committee on Water, the original constitution of which was broadened and improved in 1937 when it became the Central Advisory Water Committee, with a mandate to advise the Government on water and water legislation. It proceeded rapidly to produce a series of reports which have formed the main inspiration of the White Paper. Meanwhile, in 1935, the efforts of certain engineers and geologists resulted in the foundation of the Inland Water Survey, with the object of procuring and publishing information, particularly concerning river

flows and their variations. An excellent start was made with the Surface Water Year Book (1938), further publication of which was unfortunately suspended by the War. To this brief indication of recent efforts to collect and utilize information regarding the water resources of Great Britain, there should be added the contributions concerning underground water made over a much longer period by the Geological Survey in general memoirs and maps, in special water-supply memoirs, and since 1939 in its Wartime Pamphlets.

A fair picture is given by the White Paper of the existing chaos of water legislation and organization, with Parliament as the sole authority able to empower the taking of surface supplies (representing about three-quarters of the total), and the Ministry of Health practically responsible for underground supplies, but without adequate powers. Actual undertakings are in charge of far more than a thousand authorities, public and private, statutory and non-statutory, dealing with quantities which vary from a few thousand gallons a day to the 300 million gallons a day of the Metropolitan Water Board. Many Government departments have varying degrees of interest in water and rights of control or comment. Yet it still remains true that the private owner of land in Great Britain has unrestricted rights to do what he pleases with any quantity of water he can extract from the ground.

The White Paper proposes the revision of the general law governing water supplies (the out-of-date Waterworks Clauses Acts of 1847 and 1863), and the simplification and co-ordination of the means for their provision and control. Some progress in the first has already been made with the Waterworks Undertakings Bill of 1943. For the latter, the White Paper proposes machinery which may work well enough, given goodwill and understanding all round, but which is certainly open to the criticism of being unnecessarily complicated. The general argument on which the proposals are based, that change is undesirable unless it will lead to improvement, leads properly to the conclusion that existing water authorities should not be disturbed so long as they are providing efficient and economic service. But it does not necessarily follow that the rather haphazard group of bodies concerned with the investigation and general control of water and water-supplies should also be preserved.

The most vital proposal is that all general control should be centred in the Minister of Health, with appeal to Parliament only in cases in which matters of major policy or public interest may be concerned. The Minister is to be given wide powers to promote and authorize the provision of supplies, to require amalgamation of undertakings, to survey their efficiency, to protect resources, and to require information from users and sinkers. He is to be advised on general policy by a further reconstituted central advisory committee, made statutory; and on local matters by the regional committees, also reconstituted and increased in number. The investigations of the Inland Water Survey are to be promoted, and further information as to needs and supplies is to be obtained through the Ministries of Agriculture and Fisheries and of Town and Country Planning. Reference to the important geological aspects of the matter are somewhat vague. The valuable work of the Geological Survey is acknowledged and a summary of those aspects, contributed by the Survey, is included as an appendix. It is stated that the Survey will be "mainly responsible" for the provision of information regarding underground resources, though the Inland Water Survey is charged with collecting the same data. The matter is further complicated by the proposal, excellent in itself, to set up twenty-nine river boards with broad powers for the general care and supervision of river-systems. But among the duties assigned to them is the regular gauging of rivers, which is the main purpose for which the Inland Water Survey was instituted. It is indeed a little bewildering to contemplate the number of separate authorities to which the same data may have to be returned, unless very careful co-ordination is maintained.

While these incidental comments on detail suggest that the scheme is not fully matured, there can be no question of the value of the White Paper as a whole. Perhaps the most serious reflexion which will occur to the careful reader will concern the magnitude and complexity of the whole question, and a doubt whether it should be dealt with by a section of a Government department primarily concerned with quite different matters. There is much to be said for the proposal virtually common to the pamphlet of the Institution of Water Engineers and the Labour Party's "Post-War Water Policy", that there should be a "permanent Statutory Authority . . . analogous to the Electricity Commission" or a "National Water Commission". No single service is of greater moment to the nation than its water, nor does any make a greater demand for expert control.

## SCIENTIFIC RESEARCH IN BRITISH UNIVERSITIES

EVERY scientific worker will acclaim the example to British industry which has been set by the directors of Imperial Chemical Industries, Ltd., in providing for eighty fellowships at nine universities in Great Britain to be held by senior workers in certain sciences. The need for provision of this kind has been repeatedly stressed in various reports and papers on scientific and industrial research; for example, those from the Parliamentary and Scientific Committee and the London Chamber of Commerce, and in the more recent statement from Nuffield College. The debate had reached a point at which action was clearly called for, and in the scheme which is now announced, the directors of Imperial Chemical Industries, who had obviously been following the debate closely, have given a timely lead.

Study of the scheme indicates that its terms are as admirable as its generosity, and Lord McGowan's letter to the chancellors of the universities also testifies to the careful consideration which he and his

colleagues have given to the question in all its aspects. There is no confusion here between the strategy and the tactics of research. The main purpose of the scheme is to strengthen the general provision in British universities for scientific teaching and research. It is a concrete reaffirmation of the opinion so strongly emphasized in the recent report on the extension of scientific research in the University of Manchester, particularly in relation to the industries of its area, as to the relation between teaching standards and research and between industry and the universities—a report which, it will be noted, has already been endorsed by Dr. C. J. T. Cronshaw, one of the directors of Imperial Chemical Industries. As Lord McGowan's letter puts it: "Nearly three generations of experience of the administration and conduct of research have convinced us that academic and industrial research are interdependent and complementary, and that it is useless to expect substantial advances in industry without corresponding advances in academic science".

The relation between industrial and academic research could scarcely be better expressed, and the scheme encourages further the relations between teaching and research which should help to meet some recent criticism in this respect. Again, the point that in the strategy of research the first essential is to obtain men of the requisite ability is well seen in the hope of the directors of Imperial Chemical Industries that this policy, with wise selection of men as regards capabilities and tenure of office, will lead to the emergence of a body of men capable of taking high academic or industrial positions, thereby advancing academic and industrial research. If in fact such leaders are forthcoming—and there is no reason for doubting that they will be—there need be no fear that the correct tactics of research will not be devised or employed.

In seeking to strengthen the university scientific departments in whatever way each university thinks fit, the scheme makes the one prescription that the subjects of research should be "in chemistry or physics or in an allied science which has some direct relation to the manufacturing interests of Imperial Chemical Industries, Ltd., such, for example, as physical chemistry, biochemistry, colloid science, chemotherapy, pharmacology, engineering, or metallurgy". That prescription is broad enough to cover the whole scientific background of modern industry. Moreover, the universities to which this offer has been made have been selected on account of their size or metropolitan character or their geographic relation to the main centres of the Company's production. The challenge to the fuel, the metallurgical and the Yorkshire textile industries implied in the omission of the Universities of Leeds, Sheffield and Wales is unmistakable.

Only the most carping criticism could object that the scheme may further weight the balance of research in the universities in favour of the physical as against the biological or social sciences. Lord McGowan's letter indicates that nothing could be further from the minds of himself and his fellow directors in putting forward the scheme: it is rather their hope that it will be used by the universities to improve the balance of research effort, either in a particular university or between one university and another. It is difficult to conceive of a scheme better designed to safeguard the freedom of the universities in every way while encouraging the co-operation required to facilitate any redistribution of their research effort in accordance with a broad programme based on national needs. It will not escape notice that among the subjects of research enumerated are included some to which Sir Ernest Simon and others have already directed attention with the view of eliminating redundancy, promoting the effective development of existing schools and the provision of new schools to fill recognized gaps, through university consultation and co-operation.

The evidence of close and wise thinking which characterizes the whole scheme should commend it unreservedly to scientific workers. It is hard to imagine a scheme which could provide a more stimulating example to British industry and more practical encouragement to the scientific work of the universities, while avoiding any interference with their freedom of work; or at the same time provide for immediate action without prejudice to the large questions of strategy which are still being debated.

On the heels of this statement from Imperial Chemical Industries, Ltd., on research comes the announcement from the Bank of England that it is setting aside £100,000 for the establishment of a trust fund for the promotion of economic research (see p. 175 of this issue). In this case the trust will award fellowships, and there is no stipulation that the research is to be carried out in university institutions; but there is little doubt that the universities will benefit from the increased facilities for research in economics. Chemical industry and high finance have thus endorsed the claims of research: it is surely not too much to expect that the example they have set will be studied carefully—and acted upon—by industry in general.

## MINING AND MINERS

### The History of Miners' Diseases

A Medical and Social Interpretation. By Dr. George Rosen. Pp. xii+490+17 plates. (New York: Schuman's, 1943.) 8.50 dollars.

THIS history covers a wide field. Part 1 begins with neolithic times, when the flint miners apparently suffered from silicosis, which is hence the oldest known occupational disease. The author then discusses the mining situation during the Middle Ages and the Renaissance, and finally reviews the investigation of miners' diseases during the seventeenth and eighteenth centuries. Part 2, which forms the bulk of the work, is confined to the nineteenth century, and deals with mining and miners, the diseases of miners, and the beginnings of social and protective legislation. Most of the important work on these subjects, however, belongs to the twentieth century, and we endorse the hope expressed by Prof. Sigerist in his introduction that the author will now write a second volume in which the history of the last fifty years will be discussed.

Dr. Rosen is presumably an American, and his book is published in the United States; but it is confined entirely to the mining industry of Europe and Britain, the latter country predominating. He has produced a fascinating, restrained and well-documented work, but one which attributes little credit to those responsible for the development of the mines. For a long time Parliament was not aware of the shocking conditions under which the miners worked and of the sufferings of these unfortunate men above as well as below ground, and even when the facts were disclosed, and ignorance could no longer be pleaded, the very moderate remedial measures proposed were whittled down in both Houses, and no serious attempt was made to enforce them when they became law. Very young children were made to work underground for eighteen hours a day, and, as one author remarks, the diseases contracted in the mines compelled the men themselves to quit the pits between the ages of forty and fifty, and led them slowly but cruelly to the grave. The medical profession itself was singularly unfortunate in its researches. For many years it was denied that the black lung of coal-miners was the direct consequence of their occupation, and, when this was ultimately disproved, it was held that any inhaled dust was not only harmless but might even be beneficial, and the victims of pulmonary tuberculosis were recommended to spend a part of their time in the mines inhaling a foul and dust-laden atmosphere. It took decades of research to establish the simple fact that the pulmonary organs of coal-miners were impregnated with coal dust, and no solution of the problems of pulmonary anthracosis was possible until the extraneous origin of miners' black lung had been irrefutably established.

In 1813, Pearson had asserted, as the result of chemical experiments, that coal dust entered the lungs with inspired air, but the crushing authority of Virchow delayed the recognition of so obvious a truth for many years, until even he himself was finally constrained to withdraw his opposition. Dr. Rosen points out that it was not until the sixteenth century that we have any clear information of the occupational diseases of mine-workers. This knowledge we owe to the works of Paracelsus (1533–34) and Agricola (1556), the latter being responsible for the first complete treatise on mining. Incidentally, he refers to the presence of venomous "ants" in the silver mines, which were possibly a species of Galeodes.

Paracelsus was the first to investigate miners' diseases in any detail, and he deals with a well-defined occupational group—the mine-workers and smelters. He recognized two common types of miners' diseases, one associated with the respiratory tract and the other with acute and chronic poisoning due to the ingestion and inhalation of poisonous metals. Few miners reached middle age, and Fallopius found that most of the workers in the quicksilver mines died from mercury poisoning after three years in the pits. Stockhausen, who laboriously describes the revolting conditions under which the Prussian miners lived and worked, could only offer them the fatuous advice to "avoid all dust and fumes and live in such a manner that they will retain their strength"; and as to the presence of demons and ghosts in the pits, they must seek refuge in prayer and fasting.

In the seventeenth century a significant train of events was brought about by the prevalence of Cartesian views in physiology, according to which the human body was interpreted as a purely mechanistic complex. Physicians were thus induced to take up the study of mechanics, and this in turn led them to occupational diseases. Nevertheless, the seventeenth and eighteenth centuries produced nothing of importance in the treatment of miners' diseases, which was still based on Paracelsus. This was due partly to a serious decline in the mining industry itself, but also to the absence of any system of scientific pathology. The investigation of miners' diseases, in fact, practically came to an end, and was not resumed until the thirties of the nineteenth century. In this century the great expansion in the mining of coal, due to the industrial revolution, revived an interest in the welfare of the miners. Coal was the basic factor in the situation, and Dr. Rosen traces the history of coal-mining in England as the country in which the most important developments occurred. Attention now began to be directed towards solving the vital problems of drainage, ventilation and underground haulage, with the result that steam-power was introduced, and mining engineering moved forward to occupy a prominent position in the organization of the mines.

Dr. Rosen has not told us much of the parasitic diseases of miners. He mentions that ankylostomiasis (hookworm disease or miners' anæmia) appeared in Hungary in 1786, and that there were epidemics of it in the coal mines of France in 1802 and 1820, by which latter date the disease was known to be widespread in France, Belgium, Hungary and Germany. It was not until 1882 that Perroncito showed that it was due to the nematode parasite discovered by Dubini in 1838 (published 1843). But the solution of this trouble belongs to the following century, with which the author has still to deal.

This important contribution to the history of medicine and sociology has been admirably produced by the publisher, in spite of the fact that good paper, printing and binding seem almost to have vanished from the earth. F. J. Cole.

## PROGRESS OF HUMANITY

**Progress and Archæology**

By Dr. V. Gordon Childe. (Thinker's Library, No. 102.) Pp. vii+120. (London: Watts and Co., Ltd., 1944.) 2*s*. 6*d*. net.

THIRTY years ago, most books on prehistory dealt exclusively with accounts of the various sequences of cultures which had been determined, and with the study of the material relics left by these ancient peoples. Nowadays the approach has shifted. There appears to be a greater desire to view the subject from a more human point of view. Of course, any evidence from the remote past, other than that furnished by relics which can survive, and have, must necessarily be somewhat conjectural; but so much has been learned about our forerunners and early ancestors that the attempt to visualize them as living men and women, not so unlike many of the primitive folk of to-day, is not so absurd as might at first be supposed.

The little volume under review is written by one of our foremost prehistorians, and he is here considering the progress of humanity. Certain vital aspects of life are dealt with in their relation to early man. Thus there are chapters dealing with the food quest, tools and materials, warmth and shelter, inter-

course and diffusion of cultures, funerals, sacrifice, etc. All the time, it is suggested, man accumulated knowledge which, notwithstanding temporary setbacks, was not forgotten.

Naturally, one cannot expect that in such a small volume chapter and verse could be given for every statement of fact made, and sometimes perhaps the peg upon which much theory has been hung is somewhat slender! For example, it has been suggested that certain reindeer found in a lake near Hamburg had stones attached to them and were sacrifices, and Prof. Childe seems inclined to accept the suggestion. Frankly, the evidence seems to be open to other interpretations, and one would like to be much more certain that the stones were really attached to the beasts with this intention. Excavators—even with the rigid discipline obtaining to-day—must exercise some imagination when attempting an explanation of what they find. Moreover, a tentative suggestion made by one author sometimes appears as a proved fact in the pages of another! When important conclusions hang on comparatively slender evidence, the student must, of course, remain severely critical.

It seems to me, when tracing the path of human discoveries and progress, that mass desire has often been the important factor. Once something is definitely wanted, again and again it has been produced in an extremely short time. Consider how very quickly after the discovery of the smelting of copper came the knowledge that the better material was bronze. Did a long period of goldsmiths' experience precede the making of the treasures of the royal tombs at Ur? How speedily did that scientific toy, wireless, once produced, become an everyday product capable of being manufactured by almost anyone! And this line of thought is applicable equally in the realm of ideas as in that of technical progress—in *intelligence* as well as in *habilité*. Conversely, nothing will teach the Bushmen of South Africa to plant and herd. They have no desire to do so. The difficulty nowadays is to direct the mass desire aright along a true, if unsurveyed, line of human progress. To ponder for a time on the problems of cultural evolution in the remote past with such a master of his subject as Prof. Childe does help us to orientate our minds, when we try to foresee the lines of development along which should run the future course of the progress of mankind.

M. C. BURKITT.

# DICTIONARY OF BIOCHEMISTRY

**Dictionary of Biochemistry and Related Subjects**
Edited by Prof. William Marias Malisoff. Pp. 579. (New York: Philosophical Library, Inc., 1943.) 7.50 dollars.

THIS 'dictionary' is a new and interesting venture and it is illustrative, perhaps, of the remarkable progress of biochemistry during recent years that such a dictionary should even have been contemplated. No one now would, I think, question that there is room in the literature for a book which will define clearly biochemical terms, give references to key papers dealing with investigations on the manifold aspects of biochemistry, describe succinctly biochemical laboratory tests in current use and, above all, give brief and accurate accounts of the present position of a large variety of biochemical topics. The task of producing such a book must indeed be formidable, for the greatest care is required to secure a balanced treatment of the topics and not to give undue importance to subjects and terms of little or fleeting importance, to insert only what is relevant to biochemistry and to omit the trivial.

Much care and thought clearly have been expended on the compilation of this dictionary, which does its best to steer a middle course between a glossary of terms and an assembly of review articles. Several thousand terms have received attention, and a large number of chemical tests of more or less importance in biochemistry have been described. The terms cover the field of biochemistry and invade neighbouring fields of anatomy, physiology, botany and zoology. The list of biochemical tests in current use is fairly comprehensive but by no means complete. For example, a description of the familiar Rothera test for acetoacetic acid is missing, nor does there seem to be an adequate description of current tests for thiol compounds. Moreover, the tests which are described often lack experimental detail so that little use can be made of them. Inclusion of references in all tests is obviously a necessity.

Certain topics are distinguished by having signed semi-review articles allotted to them. Thus amino-acids are dealt with by Van Slyke, autolysis by Bradley, carbohydrate metabolism by Barker, respiration by Gerard, cellulose decomposition by Norman, etc. Unfortunately, there is only a small number of such authoritatively treated articles. Further, the topics dealt with in this manner are ill-balanced in treatment, some topics receiving ten pages or more of discussion while others, equally interesting to the student of biochemistry, are discussed in a few short paragraphs. Many important topics receive the scantiest consideration. Thus the subject of glycolysis, which is certainly worthy of detailed treatment in a dictionary of biochemistry, is dismissed in a phrase: "Breakdown of sugars in body". This is scarcely compensated for by the article on carbohydrate metabolism, which only touches upon the chemical mechanisms of carbohydrate breakdown in the cell. Should the reader look up the term 'fermentation', he would be directed to 'microbiology', under which term he would certainly learn little of fermentation. 'Fat metabolism' receives sketchy treatment in an article on "Carbohydrate and Fat Metabolism and their Reciprocal Integration" by Witzmann.

The main body of the dictionary is taken up with definitions, cross-references and short descriptions, some of which are good, some very good, and others too poor to be regarded as of informative value. The reviewer also feels a definite dislike to the inclusion in a biochemical dictionary of such abbreviations as ADP, ATP, TPN, GSH, etc., which while useful in a scientific article (where they are defined) as leading to economy of space, cannot yet be regarded as internationally accepted symbols of the substances they represent.

Considerable cutting of the irrelevant material, inclusion of many more authoritative and comprehensive articles on the more important aspects of biochemistry, attention to the inclusion of key references and constitutional formulæ (which are mostly conspicuous by their absence) and elimination of descriptions of chemical tests not in general usage, would make this dictionary far more valuable and acceptable to the student and to the research worker.

J. H. QUASTEL.

# HEREDITY, DEVELOPMENT AND INFECTION

By Dr. C. D. DARLINGTON, F.R.S.
John Innes Horticultural Institution, London, S.W.19

## 1. Three Levels of Heredity

THE development of genetics has depended on the separation between determinants and what they determine, between factor and character, between gene and gene-product, between genotype and phenotype. Once the separation had been admitted in theory the connexion could be examined in practice.

This examination has proved that there are three systems or levels of determinants[1]. The first system and highest level is that which is most accurately and equally distributed at the division of the cell and most equally transmitted by the two parents in sexual reproduction. It is responsible for the Mendelian heredity of genes; it determines the widest range of hereditary variation; and its equilibrium is mechanical. Its transmission (with odd exceptions) is not influenced in any regular way by external or developmental conditions. It therefore predominates in the government of heredity as well as in the government of the cell. This is the *nuclear system.*

The second system, recognizable only in green plants, is liable to be unequal in its distribution at cell division and is always unequal in inheritance, being largely maternal in transmission. Its equilibrium is best described as physiological. This is the plastid or *corpuscular system.* The third system constitutes the undefined residue of heredity, not associated with any visible bodies in the cell and hitherto supposed to be purely maternal in transmission. This cytoplasmic or *molecular system* must depend on chemical rather than on mechanical, or even physiological, equilibrium for its continuance.

The study of the plastid and cytoplasmic systems has been long delayed. For, as we now see, their properties can be resolved only in terms of a previously acquired knowledge of the nuclear system with its differentiation into chromosomes and genes. We can get to know extra-nuclear heredity only in terms of relationships. The first steps were made by the study of differences between reciprocal crosses of species or races in flowering plants. These were frequently male-sterile in the $F_1$ one way, although normal the other way. In other crosses, for example in the tomato, the difference was one of size and expressed itself both in $F_1$ and in the segregating $F_2$[2]. Or again, if the $F_1$'s were similar and normal, as in an upright-procumbent flax cross, abortion of the anthers, varying in degree, according to the races used, appeared only in a quarter of the $F_2$'s from crossing one way[3]. Thus the defect arose out of the reaction between a single, ambilinear, recessive gene from the nucleus of one parent and a matrilinear cytoplasm from the other.

The commonest markers in these cases are defects, and this suggests that the cytoplasm in heredity is to be regarded as a negative factor; but recent evidence points to a positive activity. Mather[4] finds that the cytoplasm of a self-compatible species of Petunia frequently gives male-sterility with the nuclear system of a self-incompatible species. The opposite combination is always normal. The same is true in Nicotiana[5]. Mather therefore suggests (unpub.) that the nuclear and cytoplasmic systems of self-incompatible plants are mutually and constructively related. Thus we may have to admit that the cytoplasmic system is not an obstacle to adaptation but an instrument of it.

## 2. Plastogenes

If the cytoplasm is adaptive, it obviously cannot be considered as a unit in adaptation. It must be composed of different determinants. The simplest evidence of this kind of organization, however, comes from the plastids. The plastids differ from other organs in the cytoplasm in that their separate inheritance and separate actions can be seen in individual cells. The critical step in their understanding was made by Renner[6,7].

By reciprocal crossing of two species of *Oenothera, muricata* and *hookeri*, Renner combined the ambilinear nuclei with the largely maternal plastids in four combinations, with the following significant result:

| | Nuclei *hookeri* | Hybrid |
|---|---|---|
| Plastids *hookeri* | Green | White |
| Plastids *muricata* | Green | Green |

The *hookeri* plastids thus turn white with the hybrid nucleus; but they turn green again in the next generation when restored by back-crossing to the *hookeri* nucleus. Evidently two kinds of nuclei with their genes are at work, and two equally permanent kinds of plastids. Such plastid differences imply the action of determinants or *plastogenes*, as Imai has called them[8]. How then do the plastogenes act? We might say that the nuclei control their activity. But it would be safer to say that the joint reaction of nuclei and plastogenes determines whether the plastids are white or green. The nuclei and the plastogenes are then, as Renner says, mutually adapted in each species to the production of chlorophyll, and this adaptation is upset in hybrids.

There is one way in which the nucleus might, however, be said to control the plastogenes. It might control, not their activity, but their mutation, which (as soon as we separate determinant from product) is an entirely different thing. The distinction between joint action and controlled mutation is well recognized in the relations of nuclear genes. Not only the genotype as a whole but even a specific, mutation-producing, gene can be shown to control the time and place of mutation of another gene the action of which is directly observable[9]. Control of plastogene mutation by the nucleus is unlikely in the Oenothera case, for it would require capacities in nuclei for instantaneously producing and reversing mutations in particular kinds of plastogene. If, however, we were to find delayed, and preferably irreversible, changes arising in otherwise autonomous plastids when they were in association with specific nuclei we should have evidence of controlled mutation. Such situations have been described by Imai[8,10] in barley, rice and elsewhere.

In barley the recessive 'variegated' homozygote is characterized by casual mutation in early life of some of its green plastids to white; and the plastids, being corpuscular, are sorted out to give green cells and tissues and white cells and tissues. The plastids are then autonomous. They are inherited only from the mother and they do not mutate back to green under a 'green' nucleus, which is indeed merely effective in stopping further mutation. Thus, equally in 'varie-

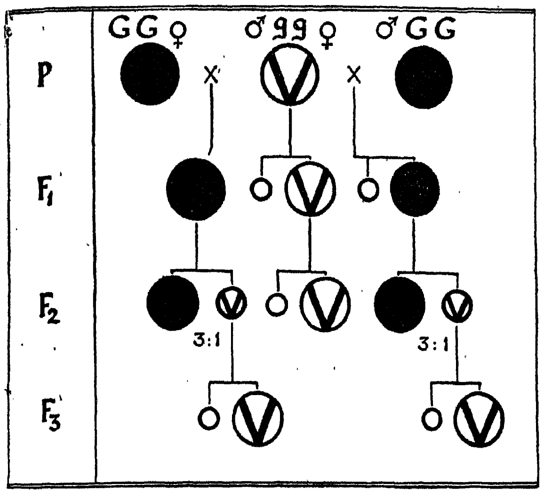

FIG. 1. *Hordeum vulgare* AFTER IMAI. BLACK CIRCLES ARE GREEN PLANTS; WHITE CIRCLES WHITE PLANTS; AND V CIRCLES VARIEGATED. SIZE OF CIRCLE INDICATES FREQUENCY OF SEEDLINGS.

gated' selfed and in its cross with 'green' pollen, a small proportion of the seedlings contain only white plastids and die; a still smaller proportion are mosaics from mixed egg cells; the rest are variegated in the selfed family, green in the cross (Fig. 1).

The same principles apply to a variegated rice[11], but a third instance in maize extends the technical possibilities[12]. Plastid equilibrium is physiological. The times and stages of mutation, and of sorting out or distribution, are both under genotypic control. They begin earlier in the maize than in the barley. Hence it gives wholly white ears which, with any pollen, bear wholly white seedlings. Late mutation, as in barley, gives egg cells having mixed plastids, green and white; these eggs, with any pollen, yield mosaic seedlings, again with some wholly white ears; and these, in the next generation, give purely white seedlings, some of which have homozygous green nuclei. Thus no kind of nucleus can make the mutated plastids change back from white to green.

In all these cases the variegated gene has a capacity (a limited capacity) for changing the plastogenes, irreversibly, from green to white. Thus the control of the nucleus is not continuous and direct but *mutafacient* and indirect. Imai, Pal, and Rhoades are able to prove this because the mutafacient capacities of the two alleles are sharply contrasted. Reactions might be otherwise if the genes and plastids concerned were recombined with the corresponding elements in the nearest relative (for example, teosinte for maize); but this could only reveal a more complex situation, not a less complex. In another variegated rice Imai has indeed shown such a complexity. Here the plastids behave like those in maize and barley, but the nuclear control is different. Individuals with non-mutable plastids arise from those with mutable plastids and the change is not controlled by a single nuclear gene. The plastids therefore simulate an autonomous mutability. Such a continuous variation in mutability, however, merely suggests polygenic control by the nucleus which in this field, as elsewhere, has hitherto been left to the account of indeterminacy.

## 3. Plasmagenes

How far are we justified in assuming the same kind of determinant in the cytoplasm where determinants are not fastened to the immediate products of their activity? If we can show that there is not only an activity relation of nucleus and cytoplasm but also a mutafacient relation, the analogy with the plastids will be broadened and the assumption of unattached determinants vindicated. This relation has now been established by Sonneborn[13] in *Paramecium aurelia*, although his interpretation, failing to distinguish between 'factor' and 'substance' in the cytoplasm, does not relate it to the present discussion.

Alternative types exist in two races of this protozoan, one of which, the 'killer' (race 51), poisons the water for the other, the 'sensitive', type (race 32). The reciprocal $F_1$'s between them are each of the maternal type. The $F_2$ in the 'sensitive' line continues entirely sensitive. The $F_2$ in the 'killer' line, however, yields one quarter of 'sensitive' individuals which behave like the original 'sensitive' type. Thus between the two races there is a gene difference as well as a cytoplasmic difference: and while the 'killer' gene *K* cannot change the 'sensitive' cytoplasm to 'killer', the 'sensitive' gene *k* can change the 'killer' cytoplasm to 'sensitive' (Fig. 2).

As in the plastid cases, this effect is not instantaneous, although it might appear so in a larger organism: it takes place in 2–5 fissions; it waits on reproduction. Thus the *K* gene is ineffective and its *k* allele does nothing beyond causing a specific and irreversible hereditary change in the cytoplasm, that is, a mutation in a *plasmagene*, or the creation of a new plasmagene. The incidence of the mutation or creation in the Paramecium cross is thus the same as the incidence of the defect in the flax cross, namely, one quarter of the $F_2$ in one direction.

Two practical points will be noticed. From the crossing of the two races it is possible to get 'killer' and 'sensitive' stocks which are both *KK* and differ only in cytoplasm. Indeed, Sonneborn has a natural 'sensitive' stock (race 47) of the *KK* type although he does not ascribe such an origin to it. Further, it is also possible to get purely 'sensitive' stocks with uniform cytoplasm and differing only in having *K* and *k*, which difference will be seen only in the $F_2$'s that they will give with 'killer' stocks. As in all such cases the effective variable may be either nucleus, or

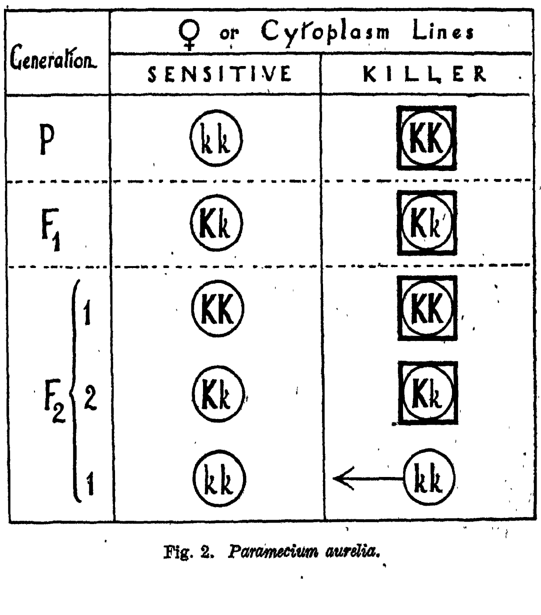

Fig. 2. *Paramecium aurelia.*

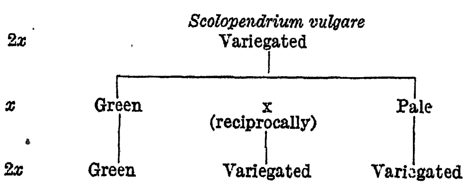
cytoplasm, or both, as we choose to arrange the experiment.

The question now arises as to how such plasmagenes maintain themselves. There are not only the two types responsible for the 'killer' and 'sensitive' reaction. Different strengths of reaction are also found in different 'killer' races. Are the plasmagenes of each of the different types uniform or can they be mixed in one individual? Here again an experiment of Sonneborn's is decisive. Permanent fusion of individuals sometimes occurs and gives rise to offspring of mixed cytoplasm. When two *KK* individuals fuse, one with 'sensitive', the other with 'killer' plasmagenes, all the progeny have 'killer' plasmagenes. Mixture is unstable and 'killer' is, we must not say dominant, but rather *suppressive*.

Thus the 'sensitive' plasmagene which is determined by the action of a nuclear gene is suppressed by the action, or by the competitive reproduction, of another plasmagene. This does not exclude the possibility that the 'sensitive' plasmagene is itself created by nuclear action.

Nine other genetic differences in five races of *Paramecium aurelia*, according to Sonneborn, show a nuclear-cytoplasmic relation similar to that of the 'killer' gene. It might not seem surprising that an incomplete subordination of the cytoplasm can survive in Protozoa or in Bacteria which have no cellular differentiation to organize. Perhaps the cytoplasm could not become the vehicle of animal development until it had largely ceased to organize heredity. A merely technical explanation is, however, sufficient. Unicellular organisms by their size, and plants by their plastids, and by the absence of such confusing elements as sex chromosomes, provide the experimental and theoretical conditions that are required for these delicate tests.

If we admit the hereditary and physiological validity of plastogenes and plasmagenes we must next look for evidence of their interaction; we must expect them to show evidence of that control of one another, mutafacient or direct, which the nucleus shows over all three levels of determinant. The fern *Scolopendrium vulgare*[14] shows such a relationship. Variegated sporophytes are pale with dark green mutant sectors. They produce two kinds of gametophyte from different whole sporangia: greens which breed true and pales which again produce variegated sporophytes, ever-sporting like the parent. Evidently there is a determinant which limits the formation of chlorophyll in the plastids. This determinant is stable in the gametophyte, but unstable in the young sporophyte. Crosses both ways between green and pale gametophytes are wholly variegated. The determinant therefore is not in the plastids. Nor is it in the nucleus, for it does not segregate at meiosis to give differences within sporangia. The determinant must be a plasmagene. Further, it must be a suppressive plasmagene since the reciprocal crosses are both of the pale type. Owing to this suppressivity even the spermatozoid is able to impress the offspring with its cytoplasmic type, and we have to admit the existence of ambilinear plasmagenes.



What does suppressivity imply? It implies that plasmagenes have rates of reproduction which can be varied widely, subject to the control of the nucleus and of one another. It implies also that their chemical equilibria must be subject in some degree to developmental as well as environmental conditions. These consequences we may now consider.

## 4. Differentiation and Mutation

The knowledge that plasmagenes can be suppressive, and hence are ambilinear, as well as mutafacient, not only raises the question of their stability or instability in development; it at once enables us to reinterpret the relevant experiments. Rogues in peas provide a starting point. They are empirically well understood[15,16]. They appear in nearly all garden varieties as more or less frequent mutations with pointed leaves and curved pods. They breed true in selfs and usually in crosses. The rogue character is therefore, like the paleness of Scolopendrium, ambilinear and suppressive in its determination. But its inheritance shows more than that. Crosses between rogues and types of the same variety give some seedlings which begin as intermediates, especially when the pollen is transmitting the rogue determinants rather than the eggs. In one variety the mutated seedlings themselves begin as intermediates which turn into full rogues before maturity. We might suppose that in these intermediate mutants and crosses the suppressiveness of rogue over type was, as in Paramecium, gradual instead of instantaneous, the unstable equilibrium being expressed in the unstable form. Breeding bears this out. The numbers of normal types in the progeny of any pod are correlated with the degree of normality of form at the level of this pod. As Bateson says, the genetic properties follow the changes of the somatic character.

Similar conditions obtain elsewhere. In rogue tomatoes suppressiveness is the other way round; type is moderately suppressive of rogue, and rogue mutation is subject to powerful environmental effects which are not yet understood[17]. But again the proportion of rogues varies with the roguishness of the plant and with the stage or state of development of any one plant. In Dahlia, Tagetes, and other Compositæ[18] breakdown of the pigmentary effector system is ambilinear in its determination, and its inheritance is correlated with its expression. But here intermediates are so stable that we cannot say that either normal or abnormal is suppressive, but only that both are slightly suppressive of the intermediate conditions. Many other analogous but more difficult cases are known[1].

If these observations have any general importance they mean that, where plasmagenes are concerned, transmission in heredity and expression in development can control one another. In doing so they are likely to defy the analytical methods appropriate to the study of either and indeed to threaten this primary boundary in biology. Already we must allow that this boundary is likely to hinder the solution of many problems now put on one side of the fence and now on the other.

It will be well, therefore, to examine other borderline cases. Among garden roses the change from the bush to the climber (not rambler) type is known in about a hundred varieties. It has the appearance of a genetic mutation. It is sudden and complete, and its occurrence is unpredictable. But its reversal is

partly predictable since the chance of reversal is greatly increased by bud-grafting on to a dwarf stock. Six out of thirty-two reverted in one budding experiment[19].

Cancer is also a border-line case on account of its heterogeneity. It ranges between two extremes. At one end it is congenital, hereditary, and highly determinate, being sometimes determined by an excess of heterochromatin[20]. At the other end it is mutational, or even invasional, and therefore inherently non-hereditary. The mutational changes may be induced in the cytoplasm of normal cells by chemical agents, the carcinogens[21], which also induce in plants dauermodifications of limited or unlimited persistence[22].

In all such cases, where the vegetative individual ceases to be the genetic unit, we have an analogy with changes that are proved to be hereditary in peas and elsewhere. How, then, are we to make the distinction between what is hereditary and what is not? Outside the nucleus it must be a physiologically trivial one. It must depend on the fact that certain self-propagating bodies, presumably nucleo-proteins in the cytoplasm, are, in one class, transmitted by the fertilized egg and, in the other class, are excluded, or liable to be excluded, from it. The distinction is physiologically trivial because, within their sphere, there are evidently different kinds of plasmagenes which vary widely in their developmental stability and selective distribution, and in their suppressiveness, or, in other words, in the type of chemical equilibrium on which they depend for their continuance.

## 5. Infection and Heredity

At this point it is worth asking how much the virus and the plasmagene have in common. In disease as well as in heredity there are three orders: nuclear, corpuscular and molecular. Viruses like plasmagenes belong to the molecular order. The chemically recognizable viruses, apart from vaccinia, chemically resemble what we know or assume of plasmagenes. They are proteins reproducing with the help of ribose nucleic acid[23], thereby being distinguished from the nuclear genes which use desoxyribose nucleic acid[24]. Viruses are subject to the developmental control of the host, being excluded from certain tissues and reduced in others. They are also subject to its nuclear control, being suppressed by some host genotypes and permitted by others, either within limits or, pathologically, without limits. There are, therefore, 'susceptible' and 'carrier' genotypes, as Baur showed in Abutilon[25]. The difference between the two types of host is genetic and may be controlled by a single nuclear gene[26]. Infection of one susceptible species can take place from another through an immune carrier species[25]. A virus, injurious to one host, can exist in equilibrium for hundreds of years with another, like the broken Zomerschoon tulip[27], damaging nothing but its chromosomes[28]. It thus becomes part of the developmental system of its host. It may be specific in its action on plastids or on pigment production, or highly generalized in its effects. It is apt to undergo mutation and consequently shows adaptation. This mutation is under the nuclear control of the host. Indeed, in the attenuation process, the nucleus is mutafacient with respect to the virus. Related viruses show suppressiveness; for example, the wild type of tobacco common-mosaic suppresses its mutants in combined infections[29]. In all these respects viruses resemble certain kinds of plasmagenes. Further, unrelated viruses may interact, and even reinforce one another, as nuclear genes do.

We are thus left with nothing to distinguish between virus and plasmagene except the two criteria used by Baur in 1906. The first is curability or environmental control as opposed to stability. But curability is rare in the absence of the antibodies produced by animals. Hot water may kill a virus without killing such a host plant as the periwinkle, for example. Similarly, Baur found that infected Abutilon, from which variegated leaves are regularly removed in a dim light, eventually produces green leaves which remain green in full light. The disease is curable.

The cure has two physiological analogies. On one hand there is chlorosis determined by nuclear genes, where the destruction of the chlorophyll likewise seems to depend on its own production: it can be stopped by low lighting, but, of course, the cure is not permanent[30]. On the other hand, there is the known environmental control of mutation or reproduction in plasmagenes. Putting the two together, we see that cure of the virus is merely the removal of the conditions of reproduction in the cell.

The second criterion is infection or invasion as opposed to inheritance. Regular transmission of viruses by the egg of the host plant (the insect vector does not concern us unless it suffers) probably does not occur, and only in a Phaseolus mosaic disease is the virus said to be transmitted by the pollen[31]. Clearly, regular inheritance of a regularly unfavourable virus, combined with infection, is an unstable condition which can end only in the whole species, either becoming adapted to carrying or resisting[31] the virus, or being extinguished by it. In the first case, the virus will have become part of the host's heredity. Both situations are found in the viruses of bacteria the rapid reproduction and adaptation of which make them observable[32].

## 6. Molecular Origins

Is there, then, between the infective virus and the inherited plasmagene an ultimate and absolute distinction? The answer is given by experiments with grafting. The transmission of viruses by grafting, confirmed as we have seen by Baur, was first noted in 1720 by Blair, who explained what he saw well enough: "'Tis by the descent of the particles from the graft, and their reascent, that the variegations appear in the other parts of the shrub"[33]. Apart from cases of variable threshold and doubtful conditioning, such as the rose mutation already quoted, a graft invasion is established in holly, privet, jasmine, laburnum and Abutilon as the cause of variegation. Now grafting is not a natural process but a human invention and a very recent and restricted one. Any virus which can be transmitted only by grafting must therefore have arisen from grafting, that is to say, from the invasion of one plant by the proteins of another.

The experimental evidence of such an expected origin of a virus is provided by the potato 'King Edward', a clonal variety, at the time of the experiments about thirty years old. The whole of this clone carries particles which, if transferred to other clones by grafting (and no other means is possible) produces

disease[34]. What is a stable and presumably useful cell protein with one plant genotype acts as a destructive agent with another. Just, in fact, as plasmagenes do.

The same principle applies to the origin of the viruses causing the Rous sarcoma[21] and presumably mammary cancer in mice. Since they are transmitted, the one only by injection, and the other only by injection or through the milk, they can scarcely have arisen otherwise than from the cell proteins of the fowl, or the mouse, in which we find them.

These viruses are distinguished from plasmagenes not by their origin or action but only by their transmission. There is therefore nothing surprising in the fact that reproductive particles can suddenly appear in the cytoplasm by the action either of the mutafacient nucleus or of external carcinogens, nor again that such particles may either be transmissible or only transplantable.

The grafting of related species of plants throws light on the position of more beneficent particles. Stocks of *Phaseolus lunatus* confer their own symbiotic specificity on scions of *P. vulgaris* and on the seedlings of these scions, and vice versa[35]. Here we have to suppose that a normal and necessary cell particle has become both infectious and hereditary, both a virus and a plasmagene, at one stroke.

The ultimate distinction between plasmagene and virus therefore seems to be the accidental one of transmission by heredity or by infection, in respect of which both are variable and both differ from their ancestral cell proteins which were used merely in development (Fig. 3). The plasmagene is a protein which can be made outside the nucleus and comes to be inherited through the egg. The virus is a similar protein which is capable of being acquired later. It is a protein which prospers through being in the wrong organism and gets there by infection[1,29]. Both classes are, of course, immensely heterogeneous. In addition, both are continually arising *de novo*, rapidly evolving, as their conditions change and partly by direct action of those conditions. They are therefore bound to diverge adaptively as they get older. But rapid divergence of the two classes merely helps to justify the supposition of their common origin.

## 7. Conclusion

Proteins in the cytoplasm can now be put in a rough genetic classification. On one hand there are some proteins, perhaps the bulk, put together by the nucleus with the help of desoxyribose nucleic acid. Perhaps, as Caspersson has suggested[24,36], the larger types of protein arise from the euchromatic genes, the smaller from the heterochromatic. And perhaps, as Pontecorvo has suggested[37], the heterochromatic genes, or polygenes of Mather, are characterized by the repetition of similar and, no doubt, simple elements. They would then be more like plasmagenes. The euchromatic genes would act by the integrated effects of dissimilar elements producing complex proteins. These proteins from the nucleus need not be self-reproducing. On the other hand, there are other proteins, plasmagenes and viruses, formed in the cytoplasm only from pre-existing proteins of similar types. These molecular types depend for their reproduction on ribose nucleic acid and are conditionally self-perpetuating. But their relative quantities are under cell control; they depend on the interaction of nucleus and cytoplasm, varying

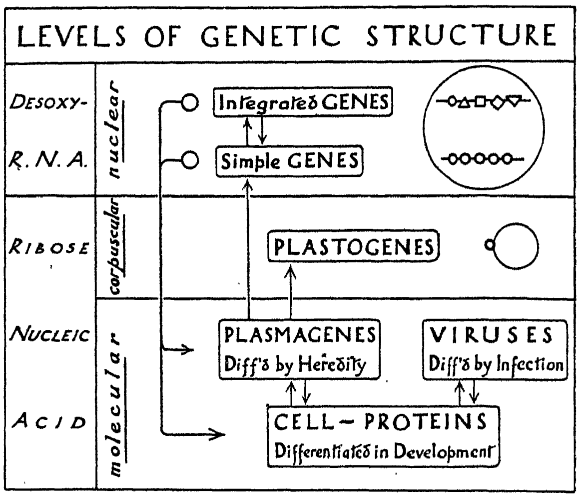


Fig. 3.

with this interaction both in heredity and development.

Between these two extremes of protein formation there are intermediate conditions where proteins, although formed by the nucleus, are potentially self-perpetuating. Their capacity for completing the life-cycle in the germ-track, and so becoming part of heredity, or for being carried by an insect, and so becoming an effective disease, will depend on suitable nuclear and cytoplasmic conditions. With limited self-perpetuation they are responsible for 'maternal inheritance' and dauermodifications.

The high frequency of plasmagene and virus mutations, aggravated by the rapidity of their selection, both under nuclear control, gives an almost Lamarckian colour to their adaptation; and in particular it accounts for their frequent and common origin from proteins in the unstable developmental zone beneath them.

To put this situation in the most general terms we must say that, at the molecular level, heredity, development and infection are under nuclear and environmental control, and that this control operates in production and reproduction, in action, in distribution, and in mutation. Further, there is interaction at the molecular level itself as shown by competition, reinforcement or suppressiveness. There is also adaptation at this molecular level and between it and the higher levels, an adaptation which obeys special rules, since mutation at the molecular level is to some extent directly determined at the nuclear level. Finally, owing to this capacity of adaptation, there is a common reservoir from which the new material of heredity and infection is continually being drawn.

The frontiers that exist between the studies of heredity, development and infection are thus technical and arbitrary, and new possibilities of analysis and experiment will arise when we have learnt the passwords to take us across them.

# PEBBLES OF REGULAR SHAPE, AND THEIR REPRODUCTION IN EXPERIMENT*

By the RIGHT HON. LORD RAYLEIGH, F.R.S.

MOST pebbles are of irregular shape; for example, in the glacial beds of flint pebbles near my home in Essex, at the most two per cent have any symmetry, and the presumption is that the large majority have not been worn down long enough or far enough to acquire it. We shall leave the irregular majority aside and deal only with those that have symmetry.

A pebble may fairly be called regular if it has three planes of symmetry at right angles to one another, but in fact most of the points of interest are exemplified by the more limited class that have circular symmetry. Such a pebble can be described by a familiar terminology, using the terms axis, poles, equator, latitude, as we use them for the earth.

As I have said, my own home is in a district where gravel beds of flint, washed out from the chalk, are abundant. A collection of such flint pebbles range from prolate to oblate forms. If a good sphere could be found, it would fill up the series very satisfactorily, but no sphere of the right size has been found. Spheres are occasionally met with, but they are much too large to fit into this series. I shall return to them presently.

From a geometrical point of view, the simplest generalization of a sphere is the spheroid, with the meridional section an ellipse, and it is natural to regard that as the typical form for a circular pebble. So long as the pebble is not too much elongated or shortened in the axial direction, we may be sure on general geometrical grounds that we shall not be far wrong in describing it as a spheroid. This hypothesis is not put to a severe test unless the polar dimensions differ considerably from the equatorial; but in such cases we find that the description as a spheroid is altogether wide of the mark. The more extreme forms are very far from being elliptical in outline. The prolate form is rather a cylinder with rounded ends, and the oblate a disk with rounded edges. That is what we find in natural pebbles.

It is not always possible to imitate Nature's operations in the laboratory—sometimes the scale is too large, and sometimes the time required would be prohibitive. This case, however, is comparatively favourable. It would take a long time to produce rounded pebbles of so hard a material as flint, but one gets on very much faster with marble, which is homogeneous and in other respects suitable. In Nature, flint is usually abraded by flint, but in my experimental work marble is not abraded with marble, but with hard steel—fragments of old files broken up for the purpose. In this way we get on still quicker, and the result is the same. What shape should we begin with? If we begin with pieces altogether irregular, a great deal of material has to be removed before a symmetrical shape is attained. This process is tedious and not particularly instructive. I have therefore begun with square prisms elongated or flattened according to whether it was desired to produce a prolate or an oblate pebble. The marble prism is put in a metal container with pieces of hard steel, and a little water as a lubricant further to imitate natural conditions. The whole is kept in slow rotation for a few days, when the marble is found to be quite rounded, the series of shapes corresponding very closely to that of the natural pebbles. The flattened disk and the round-ended cylinder appear as before, the intermediate shapes being nearer the spheroidal. A cubical block does not give a very good sphere when abraded in this way, and it has been found that there is little or no tendency for a pebble of nearly spherical form to get nearer to the sphere, so long as the process of abrasion is by churning up with other fragments—as, for example, when gravel is rolled along in water-courses.

Nevertheless, there are spherical flints found in Nature, particularly in the 'Cannon Shot Gravels' of Norfolk, which afford spherical balls two or three inches in diameter. These, I understand, are in commercial demand for use in ball mills. Such spherical flints are not thought to be shaped in Nature by attrition, for similar balls are sometimes found *in situ* in the chalk, under conditions which make it obvious that the mass as formed by chemical precipitation was spherical from the first.

Although the flattened pebbles which have been mentioned are typically found in most deposits which contain any pebbles of symmetrical shape, yet pebbles of much better approximation to a spheroid are not unknown. One or two, that I owe to Sir D'Arcy Thompson, are unfortunately of uncertain origin, but they are believed to come from mountain torrents, and this raises the question whether we can find any artificial process which will yield pebbles exactly spheroidal. I have made a number of experiments to imitate the kind of action which may be supposed to take place in mountain water-courses, in which the pebbles are whirled and tossed on a rocky bed. A cylindrical metal vessel full of water has on the bottom an abrasive bed, made of Portland cement mixed with carborundum grit. The block of marble

* Substance of a discourse at the Royal Institution delivered on March 3.

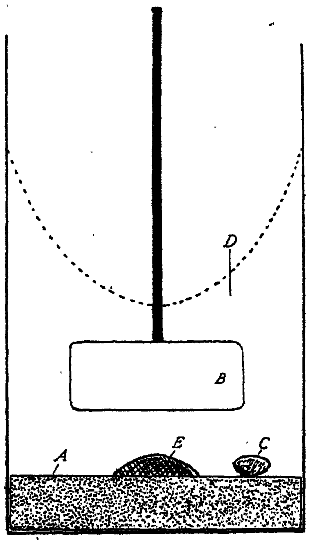

Fig. 1.

is placed on this and a violent vortex motion is maintained by a paddle driven by an electric motor (Fig. 1). The block of marble turns and rolls and skips on the abrasive bed, and in the course of three or four days it is reduced to a smooth pebble of a shape very nearly spheroidal. It differs from the spheroid in this, that instead of bulging out at intermediate latitudes like the ordinary circular pebbles, it slightly shrinks in, and may be described as lying inside the spheroid instead of outside. Clearly then, a combination of the two processes might give a very close approximation to the spheroid, and naturally occurring spheroidal pebbles may thus be accounted for.

This leads, by a natural sequence of ideas, to the consideration of pebbles worn down in potholes. Potholes, as is generally known, are cylindrical holes which are formed in the rocky beds of water-courses. They are bored out by pebbles which are carried round and round by the swirling water. They are often a foot or so in diameter and of comparable depth, but may be very much larger. I have only had limited opportunities of examining them. The pebbles found in such holes are often quite irregular. There are, however, some pretty accurately spherical pebbles preserved in the Dunn Collection, in the Mineral Department of the British Museum (Natural History), which have probably been formed in potholes, and I have been led to a laboratory study of this process. A hollow cylinder of carborundum cement was used, instead of the flat disk above-mentioned, and in this case, to save time, a lump of marble roughly spherical was used to start with. The vortex was maintained as before by a revolving paddle. The marble lump went round and round on the bottom, pressing laterally against the abrasive wall.

Let us now digress for a short time to consider how a somewhat elongated body, pivoted about its centre, will behave in a current of water. The natural man is generally inclined to say that it will set itself along the current. It is difficult to see why this conclusion seems the most natural. No doubt, if the elongated body were pivoted near one end, it would point with the longer length down-stream; but that does not help us to say what it will do if pivoted at the middle. The stream impinging on the solid body must divide and go partly to one side and partly to the other. In the case of an oblique lamina, the place of division will be somewhat upstream of the pivot. The pressure is greatest where the velocity is least, namely, at the point of division, and the pressure there will have a moment tending to set the lamina across the stream. Fig. 2, showing stream lines drawn according to theoretical hydrodynamics, will illustrate this point, though it must not be taken to represent what really happens on the down-stream side of the lamina. Moreover, it is not enough to consider only the point of maximum pressure, though this gives some insight into the matter, enough perhaps for our present purpose.

Let us now return to the lump of marble going round and round in the vortex on the bottom of the cylindrical vessel. Obviously, the stone will to some extent be retarded by friction on the bottom, and the stream of water may be regarded as passing over it, though not with the full velocity. There will then be a tendency for the stone to set itself across the (circumferential) stream, that is, radially to the vessel. Thus the longest dimension of the stone will set itself radially in the vessel, and the centrifugal force will press it against the vertical abrasive wall. The longest dimension will be continually worn down. Clearly, the stone should continually approach the spherical form; and this is what does, in fact, happen. Fairly good spheres can be made in this way. As the exact spherical form is approached, the directive couple becomes continually less. When the maximum diameter is only about three per cent in excess of the minimum, there is not much further improvement, accidental disturbances presumably being too great for the directive action to overcome. However, spherical pebbles of this degree of accuracy are equal to the very best natural spherical pebbles that I have seen, which are probably of pothole origin. Nothing so good seems to occur in any gravel deposits, though owing to present conditions there is no access to the beaches on the south coast.

Some attention has been devoted to concave pebbles. These sometimes originate in a concave fracture of flint, but it is as a rule fairly easy to distinguish such cases. There are concave pebbles which do not appear to originate in this way, and they have been imitated experimentally in marble. The same general method of experimenting was used as in the experiments first described; that is, by placing the specimen, in this case a flat parallel piece, in a metal container with the abrasive and keeping it in slow rotation, with a little water as a lubricant.

A powdered abrasive like carborundum grit or sand

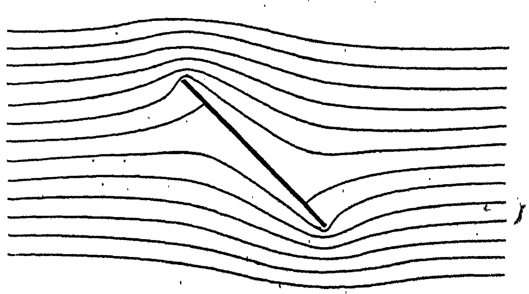

Fig. 2.

never develops a concave surface on the stone. For that, it is necessary to use an abrasive of large pieces comparable with the marble specimen itself (3 cm.). Broken flints serve very well and are easy to get. If we put a dozen such in a box with a square slab of marble, the edges and corner of the marble are, of course, rounded, but the large faces become concave.

Another instructive experiment on this subject is to use instead of marble a square of plate glass. If this is abraded in the rotating container with carborundum powder, the edges alone are pitted. This is the initial stage of the ordinary process of forming a rounded pebble. If, on the other hand, we put the glass in the revolving box with a number of sharp flints of size comparable with its own, the sharp edges have chips broken off them, which process represents the first stage of rounding the edge. In addition, we find pitting on the flat polished surface, and these pittings are more concentrated at the middle than at the edges; clearly showing the early stages of the development of a concavity.

With the view of analysing this effect, the experiment was repeated using a single flint only instead of many, and for a longer period, so that the aggregate number of pittings might be comparable. In contrast, these pittings were now found to be uniformly distributed, so that in this case no concave curvature is produced. It can scarcely be doubted that the stones other than the one which is actually operative act as a shield, and are more likely to screen the outside than the middle of the glass. In this way concavity is produced.

## WATER SUPPLIES IN GREAT BRITAIN AND THEIR UTILIZATION

A JOINT meeting of the Geological Society and the Institution of Water Engineers was held on April 19, under the chairmanship of Prof. W. G. Fearnsides, to discuss "Water in Relation to Town and Country Planning". As proposed by the chairman in his introduction, the meeting was mainly confined to a consideration of sources of water and their relation to development in Great Britain. The meeting attracted a notable attendance and produced a vigorous discussion. In addition to Prof. Fearnsides and Mr. S. R. Raffety, chairman of the Institution of Water Engineers, who briefly introduced the discussion on behalf of the water engineers, there were fifteen other speakers. They covered a wide range of topics which will be considered in order, though it may be noted at the outset that many of the outstanding aspects were indicated by Prof. P. G. H. Boswell in a well-considered opening on behalf of the geologists.

The vital dependence of populations and industry alike on water supply was inevitably stressed by many speakers. In earlier times no centre of habitation could develop unless water was obviously at hand, but now that it appears from pipes and taps the relation is overlooked with amazing frequency. Apart from their head waters, nearly all streams in Great Britain are polluted beyond any possibility of direct use for domestic and for most industrial purposes. Yet the increasing population must spread, and in certain cases industries must move, largely to areas where local surface supplies are quite unavailable. Hence underground water becomes increasingly important. Prof. Fearnsides gave an apt illustration from the Yorkshire coalfield. The growing exhaustion of the coals in the western part of the field compels the industry and population to move increasingly eastward to the coals buried under the Trias plain. The underground Trias water has been excellent, but growing demand has led to over-pumping; mining fractures the overlying rocks, and the combined result in some cases is the drawing in of water from the underlying Permian or even from the Coal Measures, with great deterioration in quality, as well as actual or threatened insufficiency.

Prof. Boswell particularly stressed the point that industrial requirements continue to increase to such a degree that a single large works may use as much water as a fair-sized town. Many instances of consequent serious difficulty have occurred, and he indicated that industrialists are very grateful for early information regarding the actual condition in areas under consideration. While the geologist may be able to give a fair assessment of a 'virgin' area, great uncertainty may be attached to some already industrialized areas where, though underground water is certainly prolific, there is complete absence of any systematic record of the heavy draughts already made. Mr. H. P. Hill, besides supporting the general theme by reference to the dependence of the older industrial areas of Lancashire and Yorkshire on the head waters of the Pennine rivers, added the valuable point that a substantial proportion of those head waters have long been impounded for the supply of canals which are now disused or decadent. Some of this water could now be used for supply.

Much of the discussion naturally ranged around the question of alternatives when adequate supplies of pure water are not available in the neighbourhood. For the really great centres of population the ultimate solution (with the notable exception of London) has almost inevitably been the use of remote upland waters. But for any smaller centres the cost of such lengthy aqueducts is forbidding. London's great contribution to the problem has been the demonstration that even highly polluted river-water may be rendered particularly pure and distributed by pumping at reasonable economic rates. It certainly points the way to one possible line of advance in certain cases. In his opening comments on the growing south-east Yorkshire towns, Prof. Fearnsides made the interesting suggestion that they may have to resort to constructing reservoirs on the middle courses of the Ouse tributaries, while Prof. W. S. Boulton (in the course of a written contribution) referred to the very considerable areas of the eastern and southern Midlands with little underground water and very variable sluggish rivers. He likewise suggested a substantial development of low-level reservoirs in such areas.

Mr. R. C. S. Walters particularly emphasized the point made by several speakers that great quantities of pure and relatively costly water are wasted, quoting the extreme case of its use for quenching gas-works coke. Like others, he commented on the danger and difficulties of 'dual' supplies of water, but hoped that the engineer might overcome it. In this connexion the use of mine water was considerably debated. Prof. Boulton referred to its extensive use for the supply of canals in the Midlands, and he had investigated its possibility for the many million

gallons required by the cooling towers of the electric stations of the national grid. Unfortunately, many analyses proved it too corrosive, and several speakers quoted similar experience in attempts to promote its industrial use. This prevailing conclusion, however, should not obscure the fact that there are industrial uses for which it would serve; nor the quite different circumstance that some mines take and contaminate good water from strata overlying the Coal Measures, which could be kept separate and utilized, as is actually done in the case of large volumes of Magnesian Limestone water tapped by certain mines in Durham.

Prof. Boulton's ultimate proposal for the cooling-tower problem was the use of purified sewage effluent, of which Birmingham provides more than 20 million gallons per day. This principle may yet be carried much further. The question of sewage control and purification is quite inseparable from the whole question of water supply in several ways. In Mr. Raffety's opening he referred to the large increase in the volume of sewage water in one area which resulted from the building-up of an adjoining district. Rainfall which formerly soaked into the land and fed the underground supplies was led into sewers, contaminated, taken away and lost for supply. In large urban areas this leads to a great reduction of underground resources. A later speaker directed attention to the fact that many important wells and boreholes are in the vicinity of rivers, and the underground waters on which they draw are liable to contamination by the polluted streams. There is no reason now why all substantial sewage should not be so treated as to produce a practically pure water. The fact that the cost of treatment cannot be immediately offset by a corresponding profit entry loses all force when weighed against the immeasurable gain to the community in amenities of all kinds, and not least in the protection of its water supplies.

The question of protection was another main theme of the discussion. Mr. R. C. S. Walters demonstrated by the cases of several of the Coventry wells that the area of intake of the underground water may be immediately around the well or in some more or less remote area in particular cases. He emphasized the need for precise geological knowledge of each case to define the region where protection from surface pollution is necessary. Dr. Buchan illustrated the pollution of the underground supplies which has resulted from the over-pumping in certain parts of east London drawing in salt water from the estuary. Prof. Boswell noted the depletion of considerable areas which results from mine drainage, and Mr. Edmunds the loss from the uncontrolled flow of artesian supplies.

Dr. G. M. Lees quoted his experience of recharging Persian oil-wells with temporary surplus petroleum, which had proved entirely successful, and suggested the replenishment of water supplies from the chalk by leading the excess of pure water available during periods of plenty into suitable disused wells. Though other speakers referred to cases in which attempts had failed, the idea seems worthy of further investigation.

Regarding the important question of water-borne disease, Mr. Raffety noted that while concern is properly felt for the safety of underground supplies in urban areas, the majority of proved cases of epidemics arising from polluted water have concerned supplies from rural sources. Mr. E. Morton observed that while the large undertakers can afford to purchase substantial areas of land or otherwise protect their sources, the smaller rural companies have not this facility. The ever-present danger of unrestricted private pumping is widely felt, and attention was directed to the unknown but probably very considerable remote effects of the concentrated pumping of such prolific areas as the Colne and Lea valleys.

The need for investigation and for the proper recording of all supplies was naturally uppermost in the minds of many speakers. All dwelt on the incompleteness of most records (making them of little value) and the extreme lack of information regarding private supplies. Mr. Edmunds commented on the special value of long-period records and on the unfounded fears which have frequently prevented disclosure of information. Dr. Buchan also gave an admirably illustrated account of some of the more recent studies of underground water-levels by the Geological Survey, extending over a wider area his well-known studies of the London region, and indicating the importance of such collated knowledge for the correct assessment of the water resources in any area.

Prof. W. B. R. King discussed the fundamental importance of systematically planned research on selected areas, including continuous rainfall and water-level data, percolation and run-off gauging, behaviour of exhaustion cones, and investigation of rock characteristics in the field and laboratory. Much might be done by the co-operation of university departments with neighbouring water authorities. Some of the work would be necessarily expensive and funds would be needed.

Sir Malcolm Watson directed attention to a matter of first-class importance in stressing the need of adequate supplies of water for agriculture. Mr. C. Green spoke especially of the part played by finance as the final deciding factor in all water schemes, and the essential ground for Government intervention.

Finally, Mr. C. E. N. Bromehead referred to some recently discovered and quite unexplained anomalies in the iodine content of certain supplies. Though the iodine amounts only to some 50 parts per thousand million, this is about seventeen times the normal, and the occurrences represent a medically important and geologically puzzling problem.

While the meeting did not proceed to the framing of formal resolutions, the vital importance of a comprehensive survey of the water resources of Great Britain, both surface and underground, was made clearly evident; as also the fact that such a survey cannot be satisfactorily complete or just unless it be made under statutory powers. Urgent demand has compelled the great cities to use their large financial resources to solve the water problem, usually by resort to long-distance impounding schemes. Hence the outstanding problems relate chiefly to 'rural' areas and widely spread industrial regions, to which such schemes cannot as a rule be economically applied. For this reason underground waters acquire an ever-increasing importance, and the time is overdue for the Government to accept responsibility for the control of water supply. Water supply must be one of the foremost considerations in every scheme of town and country planning. Uncontrolled competition for water cannot be tolerated, whether among private concerns or public companies. It can have only the most harmful results, and it reflects most seriously on those responsible for the orderly development of the country.

# OBITUARIES

## Prof. A. H. Reginald Buller, F.R.S.

ARTHUR HENRY REGINALD BULLER was born in Birmingham on August 19, 1874. His biological training included work at Mason College, Birmingham, at Leipzig, Munich, and (in 1900) at the Marine Biological Station, Naples. He then returned to Birmingham as lecturer in botany until, in 1904, he was appointed first professor of botany in the University of Manitoba.

The young and booming city of Winnipeg delighted Prof. Buller, and the cold, bracing winters suited him. He entered with enthusiasm and energy upon his teaching, which at first included geology as well as botany. He prepared all his lectures and laboratory courses with great care, and transmitted something of his scientific spirit to his students. He did much, with the few other faculty members, to promote the growth of the young University.

At night during the long winters, and in any free time by day, he devoted himself to researches on the fungi. With painstaking, persistent care, and with much ingenuity in the use of simple apparatus, he sought out the details of such activities as the production, liberation, and dispersion of spores in Coprinus and other fungi. Few could lose themselves so completely in their work as he; but, since he never married and always lived at a hotel, the missing of a meal or a night's sleep disturbed no one.

One of the attractions of the position at Manitoba was the long summer holiday which allowed him to spend three or four months each year at Birmingham, where he worked in the laboratories or library, or studied Nature in the woods and fields, commonly with his friend W. B. Grove. In later years he spent much of each holiday at Kew.

Although Buller had published several papers in scientific journals, by 1909 he had enough material for a book to be entitled "Researches on Fungi". He submitted his manuscript to a society, but was told it could not be published unless it were reduced by about half. That, he considered, would be mutilation. He therefore published the book at his own expense—and later five more volumes even larger. Many mycologists and others have found this *magnum opus* not only of great scientific value, but also eminently readable. Other books included "Essays on Wheat" and a "Practical Botany" for students.

On returning to Winnipeg each year about the end of September, he started his classes and then took advantage of the usually glorious Canadian autumns for a few mycological forays. Alone or with students, and later with members of the mycological colony which gathered at Winnipeg, he went for one or a few days into the primeval woods at Kenora or Minaki. He was a most stimulating leader of such excursions, for he knew not only the names but also the habits of the larger fungi and was always ready to spend an hour or two, even in heavy rain, to discover any new detail.

Prof. Buller gradually built up a strong department of botany and, though there was no graduate school for several years, he helped train a number of mycologists and other men of science now prominent in Canada. He took great interest in the Dominion Laboratory of Plant Pathology, which began at Winnipeg in 1923. He was always ready to help any co-worker.

Many honours came to him, including the presidency of the British Mycological Society, of the Botanical Society of America, and of the Royal Society of Canada. He was awarded the LL.D. by the Universities of Manitoba and of Saskatchewan, and a D.Sc. by Pennsylvania. He was elected a fellow of the Royal Society in 1929, and awarded a Royal Medal in 1937. His popularity as a lecturer increased through the years, and he was frequently chosen to give important lectures or lecture courses in Canada and the United States.

Buller's interests were broad. He knew by sight most of the flowering plants of England and of Manitoba, and many of the birds. He read much, and had memorized long passages from Milton and Shakespeare. He amused himself by writing verse (some of his limericks have international fame), by playing the piano, by conversation—preferably regarding fungi, but with interest on any subject. He listed his recreations as "billiards and crossing the Atlantic" and, though he found little time for the former, he made about sixty-five trans-Atlantic journeys (surely a record for a botanist). He had assumed, when he became professor emeritus at Manitoba in 1936, that his Atlantic crossings would end on an even number. However, the outbreak of war caught him at a congress in New York, so he returned to his researches at Winnipeg, varied with a number of lecture trips. In Winnipeg—which, after all, had been his main home for forty years—he developed a tumour on the brain which entailed weeks of hopeless struggle, and caused him worry because all his planned researches were not completed. He died on July 3, 1944, and is survived by a sister in London.

G. R. BISBY.

## Prof. A. E. Conrady

ALEXANDER EUGEN CONRADY was born at Burshied, Düsseldorf, on January 27, 1866. His death in London on June 16, 1944, removes one who has taken a very prominent part in the development of optical sciences in Great Britain, of which he became a naturalized subject in 1903.

His father, Edmund Conrady, ultimately left the profession of schoolmaster to manage a firm which had its business centre in Bradford, England, but A. E. Conrady's first visit to England took place while he was still an undergraduate at the University of Bonn, and later he also had occasion to travel to various parts of the world in the capacity of engineering adviser. He seems early to have developed a great interest in the design and production of lens systems, and in the early 1890's he set up in business at Keighley as "Optician and Mechanician". Somewhat later he received great assistance and encouragement from Mr. George William Brown of Leeds, with whom he entered into partnership under the name of Eugen Conrady and Co., with premises in Park Street, Camden Town. During this period he designed and began to produce the microscope objectives known as the "Holoscopic" Series, which were considered at that time to be unsurpassed in definition. He had also designed and produced a convertible anastigmatic photographic lens of aperture *f*/6·3, followed by others.

In 1898 Conrady began his long association with Messrs. W. Watson and Sons, Ltd., as chief designer and scientific adviser. The "Holoscopic" systems were and still are produced by this firm, for which

he designed many other notable systems, including a range of apochromatic objectives. During the War of 1914–18 it was early found that all the periscopes used in British submarines had been obtained from a foreign firm and that no British maker had experience of their design and manufacture; but Conrady produced very successful designs for this essential instrument and superintended the subsequent production, thus helping materially to avoid a very grave peril.

The Department of Technical Optics was founded at the Imperial College of Science and Technology in 1917 to meet the urgent need of training more optical designers for British firms, and Conrady was appointed to the chair of optical design on the strong recommendation of the late Prof. F. J. Cheshire. Conrady's first class was a summer vacation course, attended by a large number of enthusiastic students including a Senior Wrangler. Freed from the immediate pressure of an industrial post, Conrady's unrivalled practical experience flowered into original and strikingly simple treatments of optical theory.

Conrady had already had contributions to the theory of optical design published in papers in the *Monthly Notices of the Royal Astronomical Society* during 1904–5, and had thus indicated already that the main feature of his work would be the application of physical optical principles in this field. He was greatly influenced by the work of the late Lord Rayleigh, and coined the now familiar term 'Rayleigh limit' to denote the '$\lambda/4$' maximum allowable optical path difference characteristic of a good design. He worked out the relations between geometrical and physical expressions of aberration, and showed how to control the residual aberrations. A series of papers which appeared in the *Monthly Notices* during 1918–20 reflect something of the fertility of his ideas, which were, however, treated much more fully in the typed lecture notes issued to students. His well-known book, "Applied Optics and Optical Design" (Oxford University Press, 1929), was the result of many trials and experiments in presentation. His work has placed the whole subject of optical design on a far stronger basis than was previously obtainable.

Beyond the material contained in the first book, he had given, in his lectures to advanced students, more extensive material on the systematic design of microscope objectives and a new treatment of aberration theory based on considerations of optical path. It was hoped that after his retirement from the Imperial College in 1931, he would have leisure to complete this material for a second volume, but ill-health unfortunately frustrated him. The hope has been widely expressed that since some members of his family are distinguished in the fields of physics and optical design, they will be able to edit and publish the very full notes which he left.

Conrady was never happier than when lecturing to his students, emphasizing special points with a shake of the upraised forefinger. He had a keen sense of fun and humour, and he enjoyed and told many a good story. Fond of the open air, his favourite holiday frequently took the form of an extended trip with his family up the Thames in a rowing boat. He was, however, extremely shy and sensitive, shrinking instinctively from controversy.

His activity of mind made him seem somewhat inattentive to parallel work carried out by others. Faced by a question, he found it easier to obtain the answer from his own research than by reference to published literature, and indeed his writings are remarkable for their scarcity of references to investigations published by other writers. He might have been happier if his temperament had allowed him more readily to tolerate controversy and criticism, but on his retirement he withdrew completely into privacy, partly owing to indifferent health. He had lectured before the Royal Institution, and had received the Traill-Taylor Medal of the Royal Photographic Society; and it is pleasant to record that shortly before his death he was made an emeritus professor of the Imperial College of Science and Technology. But if honours were comparatively few, his most notable honour is the gratitude of many students to whom he opened paths which would otherwise have been impassable. His passing will be much to the regret of students and former colleagues.

In 1901 he married Annie, the fourth daughter of William and Mary Bunney of Harefield, who died in 1941. He is survived by three daughters.

L. C. MARTIN.

## Dr. Milan Hodža

DR. MILAN HODŽA, the Czechoslovak scholar and former statesman, died in Florida on June 27 at the age of sixty-six. The son of a Protestant pastor, Hodža was born at Sučany, in north Slovakia, in 1878 and graduated at Budapest. Circumstances led him to champion the cause of his Slovak kinsmen, whom he represented in the Hungarian parliament during 1905–14. He was imprisoned during the War of 1914–18, but when the Czechoslovak Republic was founded his advancement was rapid. Indeed, he was almost continuously in the Cabinet either as Minister of Agriculture or Education and lastly as Premier during 1935–38.

Hodža was responsible for many progressive educational measures and for various social advances such as the radical land reform in Czechoslovakia. In education, his policy was to neglect no section of the community, and to utilize the nation's resources to the financial limit. This involved the erection, equipping and staffing of thousands of new elementary and secondary schools, and the establishment of two new universities, besides various scientific institutes and research stations. In agriculture he realized the importance of the need for greater application of scientific knowledge for improved crop cultivation and stock-breeding, and he also did much to promote international co-operation among agriculturists.

His premiership coincided with critical years for his country, and when its independence was lost he went first to France, then to England and finally to the United States, where his last years were spent in writing his "Federation in Central Europe", in which he outlined a scheme for a federal co-operation among the Danubian States.

G. DRUCE.

WE regret to announce the following deaths:

Sir Ralph Fowler, O.B.E., F.R.S., Plummer professor of applied mathematics in the University of Cambridge, on July 30, aged fifty-five.

Mr. F. J. Mortimer, C.B.E., a former president of the Royal Photographic Society and editor of several photographic journals, recently by enemy action, aged sixty-eight.

# NEWS and VIEWS

## Electrical Engineering at Birmingham: Prof. D. M. Robinson

THE chair of electrical engineering at the University of Birmingham has been filled by the appointment of Dr. Denis M. Robinson. Prof. Robinson, who is in his fortieth year, graduated as B.Sc.(Eng.) at King's College, London, in 1928; he was awarded the degree of Ph.D. of London in 1930, and had industrial training at Siemens and Metropolitan-Vickers. During 1929–31 he was a research student at Massachusetts Institute of Technology, publishing a paper on "Unpolarised Resistivity of Glass". During 1931–35 he held a research appointment with Callender's Cables, Ltd., his work being published in 1935 as a monograph entitled "High Voltage Cables". Later he held a research appointment in television engineering, an experience which led to his being taken into the Air Ministry in December 1939, where he is working in the Tele-communication Research Establishment. His service, which involves frequent visits to the United States, has been connected with developments of new discoveries and the putting of these into production. He has thus been brought into contact with all the important electrical engineering firms controlling new developments. Prof. Robinson is therefore exceptionally qualified to effect the union of fundamental advances in physics with the established branches of electrical engineering.

## Bank of England Trust Fund for Research in Economics

To mark the two hundred and fiftieth anniversary of the founding of the Bank of England, the Court of Directors has decided to establish a trust fund with a capital of £100,000 for the promotion of economic research. The fund will be known as the Houblon-Norman Fund, after Sir John Houblon, the first governor of the Bank in 1694, and Mr. Montagu Norman, who retired recently after holding the office of governor for twenty-four years. The income of the fund will be used to award fellowships, probably three a year, to be known as Houblon-Norman Fellowships, for the promotion of research into the working and function of financial and business institutions in Great Britain and elsewhere and the economic conditions affecting them. Grants may also be made toward the expenses of research already in being and to facilitate publication.

Although the Bank of England will follow with interest the activities of the trust, the management of the trust will be independent of the Bank, the first trustees being the deputy governor (Mr. B. G. Catterns), Lord Eustace Percy and Mr. Samuel Courtauld. In making awards the trustees will be assisted by an expert committee, the first members of which will be Mr. Henry Clay, warden-elect of Nuffield College, Oxford, economic adviser to the Bank of England, and previously professor of social economics in the University of Manchester; Sir Hubert Henderson, recently elected professor of political economy in the University of Oxford, now serving as economic adviser to his Majesty's Treasury; and Prof. A. M. Carr-Saunders, director of the London School of Economics and formerly professor of social science in the University of Liverpool. The trustees will announce in due course when they are open to receive applications for fellowships.

## Distribution of Spindle (*Euonymus europaeus*) in Great Britain

THE Biology War Committee has been requested by the Agricultural Research Council to collect information and afterwards to plan sample surveys of the distribution of the spindle tree (*Euonymus europaeus*) in Great Britain. This scheme is part of the general research programme into the biology of the bean aphis (*Aphis fabæ* (*A. rumicis*)) which over-winters on this plant. The damage done by the bean aphis to the sugar-beet crop alone is estimated to reach a million pounds in some seasons, and proper knowledge of the distribution of its primary winter host is essential in any consideration of the problems of control. The Committee therefore asks for the following information from anyone able to supply it: (1) The exact location (reference one inch or six inch map if possible) of areas which can be put in the following categories: (i) spindle totally absent; (ii) spindle rare or occasional (isolated bushes 1–2 plants per square mile); (iii) spindle frequent (intermediate density between (ii) and (iv)); (iv) spindle unusually abundant (at least a hundred bushes per acre or ten plants per 100 yards of hedgerow); (data for *Euonymus* spp. in gardens should not be included). (2) The proportion by area which falls into each of the four foregoing categories of density. (3) The differences in (*a*) geological formation, (*b*) soil, (*c*) drainage, (*d*) altitude, (*e*) aspect, (*f*) other factors, which might influence the distribution of spindle. Such information should be sent before August 31 to Mr. G. E. Blackman, Hon. Secretary, Biology War Committee, Imperial College of Science and Technology, London, S.W.7.

## Scientific Books and Papers for China

THROUGH the Cultural Scientific Mission to China of the British Council, British men of science have learned of the great difficulties under which their Chinese colleagues are labouring to-day. Of the many obstacles to the pursuit of science in war-time China, not the least important is the scarcity of standard text- and reference books, and journals and reprints, which, equally with technical apparatus, are necessary for scientific teaching and research. The Natural Science Society of China (British Branch), through its president, Dr. S. P. Chu, and honorary secretary, Mr. P. M. Yap, is appealing for scientific and technological publications, which readers of *Nature*, either individually, or as organizations, can spare, to be sent to China. The great majority of Chinese scientific workers are accustomed to English texts and literature; indeed, many of them have obtained a part or the whole of their training in Great Britain, and the response to this appeal will be of significance, not merely as an expression of comradeship between British and Chinese scientific workers, but also as a constructive effort towards rehabilitating science in Free China. The British Council, 3 Hanover Street, London, W.1, has offered to receive on behalf of the Society such scientific literature as may be available; and it will be dispatched as opportunity offers to the Science Library of the Natural Science Society of China in Chungking.

## Determination of Distance by Radio

THE issues of the *Journal of the Franklin Institute* of January and February 1944 contain an article by C. D. Tuska entitled "Historical Notes on the Determination of Distance by Timed Radio Waves". This

article traces the historical development of methods of measuring distance by means of radio waves using both the frequency modulation and amplitude modulation or pulse methods. It is now about twenty years since the classical experiments of Appleton and Barnett provided a direct measurement of the height of the reflecting layer in the ionosphere using the frequency variation method; while, shortly afterwards, Breit and Ture demonstrated the use of short trains of waves of about one millisecond in length for making the same type of measurement. Many variations and improvements on these two methods have been made from time to time by those engaged in studying the properties of the ionosphere as a medium for reflecting radio waves back to the earth's surface. Methods based on the same principles have also been used for determining the altitude of aeroplanes by reflecting waves from the ground beneath. The article referred to above describes briefly the various methods which have been devised to meet these applications by the aid of a review of the published scientific literature, and especially of the publications of the United States Patent Office for the past ten years or so. As the author states, the notes are necessarily incomplete for the war period, on account of the scarcity of publications for security reasons. The bibliography of eighty-one references appended to the article may, however, be useful to those concerned with tracing the historical development of a comparatively modern application of radio science.

## Institute of Ophthalmology at the Royal Eye Hospital

THE immense clinical material and the considerable research activities at the Royal Eye Hospital have prompted the Council of the Hospital to initiate the establishment of an Institute of Ophthalmology, where teaching and research can be carried out systematically and co-ordinated with the work of laboratories and of other ophthalmic and of general hospitals. The Institute will have an independent Board of Governors; and panels of scientific, medical, surgical and ophthalmic advisers have been set up to help in planning and carrying out the work. The Institute will be open to all ophthalmologists, and offers of co-operation will be welcomed.

## Beit Memorial Fellowships for Medical Research

THE following elections have been made to Beit Memorial Fellowships for Medical Research, with permission for each fellow to be seconded at any time for war duties: *Fourth Year Fellowships* (£500 a year): Dr. W. Holmes, to continue the study of the regeneration of nerve fibres after injury (Department of Zoology and Comparative Anatomy, University Museum, Oxford); Dr. Mary F. Lockett, to continue the study of renal pressor substances responsible for experimental high blood pressure (Pharmacology Laboratory, Cambridge). *Junior Fellowships* (£400 a year): Dr. J. C. Boursnell, to study the fate and functions of trace and some other elements in the animal body, using radioactive isotopes (Department of Biochemistry and Chemistry, Medical College of St. Bartholomew's Hospital); Dr. G. A. Levvy, to study the adaptive enzymes in the animal body with special reference to the role of glucuronidase in the metabolism of steroid hormones and related substances (Department of Biochemistry, University of Edinburgh); Dr. H. J. Rogers, to study the biochemistry of hyaluronidase obtained from various sources, and the role of enzymes such as hyaluronidase and lecithinase and other bacterial antigens in infection (Lister Institute, Elstree, Herts); Dr. G. J. Romanes, to study the relationship between the developing mesoderm and the motor apparatus of the spinal cord supplying it (Department of Anatomy, University of Cambridge); Dr. F. Sanger, to study the chemical structure of proteins with special reference to insulin (Sir William Dunn Institute of Biochemistry, Cambridge); Miss S. P. V. Sherlock, to study the hepatic function in disease by biopsy methods (Department of Medicine, British Postgraduate Medical School); Dr. Charity Waymouth, to study the factors influencing tissue growth *in vitro* (Physiology Department, University of Aberdeen); Mr. E. C. Webb, to study the ultimate mode of action of drugs and poisons in living tissues (Sir William Dunn Institute of Biochemistry, Cambridge).

The Trustees, in their annual report for the year 1943–44, refer to the election this year of Prof. G. F. Marrian, professor of biochemistry in the University of Edinburgh (fellow 1917–20), to the fellowship of the Royal Society. They accepted with great regret the resignation of Prof. T. R. Elliott, who has been secretary to the Advisory Board since 1930, and whose experience and wisdom had been of inestimable value; his place on the Board has been taken by Sir Thomas Lewis, and Dr. A. N. Drury, director of the Lister Institute, has been appointed acting secretary.

## Announcements

DR. NORMAN ALLEN, of the Research and Development Laboratory of the Mond Nickel Company, Ltd., has been appointed superintendent of the Metallurgy Division at the National Physical Laboratory. He will take up his duties on September 1, 1944.

THE honorary degree of doctor of science has been conferred by Columbia University, New York, on Dr. L. J. Briggs, director of the U.S. Bureau of Standards, and Te-Pang Hou, who was trained first in China and afterwards in the United States, and eventually established in China a modern chemical work.

THE Royal Institution has established nine graduate memberships, three of which will be awarded annually to recent graduates, of either sex, of any university in the British Empire who have taken a degree with either first or second class honours in any scientific subject. The membership will give the holder the full privileges of members of the Royal Institution for a period of three years, with the exception of the right to attend or vote at any meeting of the members. The first three graduate memberships will be awarded about November 1944 to students who have graduated in 1944. Application forms can be obtained from the General Secretary, Royal Institution, 21 Albemarle Street, London, W.1.

ERRATUM. In the communication "'Fluorine-like' Action of Various Substances on the Teeth" by Prof. J. T. Irving, in *Nature* of July 29, last paragraph but one (p. 150), line 17, the word "not" should be omitted, and the phrase should read ". . . the other substances here examined also act only by altering the composition of the blood . . ."

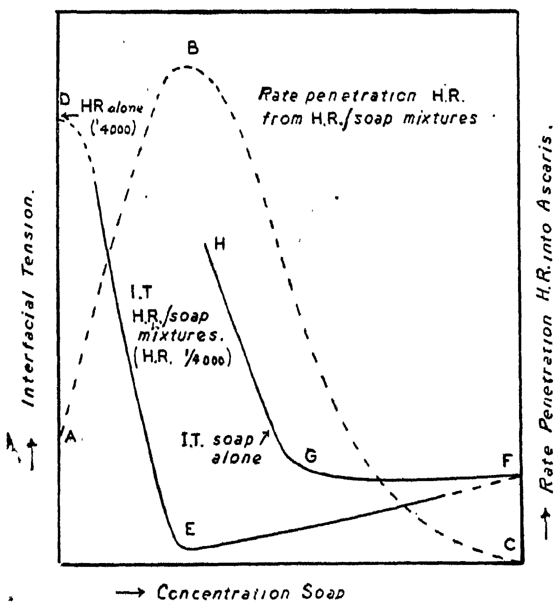
## Effect of Soaps and Synthetic Wetting Agents upon the Biological Activity of Phenols

AN investigation into the anthelmintic action of hexyl resorcinol, in particular as modified by the presence of soaps, leads us to suggest a simple and apparently general explanation of the numerous, often contradictory, results previously recorded upon the biological activity of soap/phenol systems. (The term 'soap' here covers both the natural soaps and the synthetic detergents.)

Measurements of the rate of penetration of hexyl resorcinol into the pig roundworm, *Ascaris lumbricoides* var. *suis*, alone and in the presence of soaps (sodium cholate, sodium oleate and cetyl trimethyl ammonium bromide) have been carried out, and in addition measurements, under parallel conditions, of interfacial tension against an inert mineral oil ('Nujol'). A similar behaviour is shown with all three soaps and is illustrated diagrammatically in the accompanying figure.



Considering a fixed concentration of hexyl resorcinol (for example, 1/4,000), the principal points can be enumerated as follows: (*a*) On increasing the soap concentration from zero, the biological activity, as measured by the rate of penetration into Ascaris, rises from its initial value $A$ to a *maximum* at $B$. (*b*) Over this range of soap concentrations, the interfacial tension falls to a *minimum* at $E$. (*c*) The maximum accelerating effect of the soap, as indicated by the difference between $B$ and $A$, is in the order cholate $\ll$ oleate $<$ cetyl trimethyl ammonium bromide. (*d*) The maximum lowering of the interfacial tension (at $E$) is also in the order cholate $\ll$ oleate $<$ cetyl trimethyl ammonium bromide. (*e*) The minimum interfacial tension of the hexyl resorcinol/soap mixture is markedly lower than that of either of its constituents, indicating 'complex' formation in the interface[1]. (*f*) With increase of soap concentration beyond that corresponding to $B$ (or $E$), the biological activity falls to zero ($BC$ in figure). (*g*) Over this range of soap concentration, the interfacial tension rises ($EF$ in figure), ultimately reaching a value which approximates to that of the soap alone. (*h*) The critical concentration for micelle formation is lowered by the presence of hexyl resorcinol (from $G$ to $E$ in the figure).

It is clear that the rate of penetration of hexyl resorcinol is intimately related to the interfacial activity of the soap/hexyl resorcinol mixture, thus readily accounting for the part $AB$. As the soap concentration is increased beyond that corresponding to $B$ (or $E$), the interfacial tension curve shows that micellar aggregation sets in, and the hexyl resorcinol, being present in fixed amount, will distribute itself between the micelles and any other interface present (for example, oil/water or Ascaris/water), thus tending to raise the interfacial tension and hence to *diminish* the rate of penetration. Further increase in the soap concentration will increase the proportion present in the micellar form, until ultimately effectively all the hexyl resorcinol is held by the soap micelles, the mixture consequently showing negligible reduction of interfacial tension from the value for the soap alone (point $F$), and also negligible biological activity (point $C$). (The soaps alone penetrate Ascaris comparatively slowly, if at all.)

This simple picture of a competition between micelles and biological interface should be of general validity not only for all types of phenols but also for other biologically important compounds when present in aqueous soap solutions (for example, in certain insecticidal sprays, and possibly also in fat absorption). Whether the soap is already present in the system (for example, as bile salt or fatty acid), or is added intentionally, is immaterial.

Examination of the literature shows many phenomena which appear to be explicable upon this simple picture. For example, Frobisher[2], studying the activity of phenol/soap mixtures against *B. typhosus*, found an optimum soap concentration. (His explanation for the inhibition by the higher soap concentrations—a coating of the bacteria surface with a more or less solid soap film acting as a protective covering—must be ruled out in the light of more recent surface chemical concepts.) Billard and Dieulafe[3] showed that the toxic effect of curare injected into guinea pigs intraperitoneally could be accelerated by the addition of low concentrations of soaps but decreased by higher concentrations. Bellows and Gutmann[4] showed enhanced penetration of sulpha drugs into the cornea in the presence of certain detergents. There are also numerous recorded cases of the *decrease* of the bactericidal activity of phenols by soaps[5], which likewise are readily explicable on the above principles.

Concerning the ultimate origin of this enhanced biological activity of hexyl resorcinol and other phenols in the presence of suitable concentrations of soap, various possibilities have to be considered. For example, the phenol may penetrate by a normal diffusion process, the greater surface activity of the complex serving merely to increase the concentration at the biological interface; or it may penetrate by means of a two-dimensional interfacial spreading[6], the diffusing unit now being the soap/phenol complex. On either picture the acceleration should run parallel with the interfacial activity, as found experimentally

(c and d above). The fact that soaps penetrate Ascaris slowly, if at all, even under the optimal conditions for penetration by hexyl resorcinol, would appear to discount the latter; but the whole question is necessarily complex and warrants a more detailed discussion than space permits here.

The results outlined above, to be detailed in a forthcoming publication, emphasize the importance of 'complex' formation in biological activity, as shown earlier by Schulman and Rideal[1] in their study of hæmolysis and agglutination.

## Formation of Aluminium Hydride Layers on Aluminium

SCHULLER and his co-workers[1,2] have shown, from spectroscopic studies by the hollow-cathode technique, that hydrogen molecules forming the aluminium hydride bands come from the metal itself. I had come to a similar but more definite conclusion some time earlier, and had observed that hydrogen molecules formed a layer of aluminium hydride spaced between the well-known aluminium oxide layer at the surface and metallic aluminium underneath.

The following is an account of my recent experiments. An aluminium plate as cut from ordinary sheet aluminium and a carbon rod formed the electrodes and potassium hydroxide solution the electrolyte. The carbon rod was kept in the solution and afterwards the aluminium electrode was quickly introduced and the ensuing voltages noted. In one set of observations, when a normal solution of potassium hydroxide was used, the voltage immediately came to 0·8, rose to 1·254 in two minutes and a half, fell to 1·2 in three minutes and a half, and then remained constant except for a small decrease due to polarization.

The voltages of 0·8 and 1·2 clearly correspond to aluminium oxide and pure aluminium respectively, measured with respect, of course, to carbon, the latter voltage appearing when all the upper layers have been consumed by chemical action. The voltage 1·254 is then due to a layer which is neither of the two. On the theory of oxidation-reduction potentials, or even on prior considerations, it is clear that the layer must be a compound of aluminium of a more reducing character than aluminium.

It is presumably aluminium hydride. The following observations confirm the above findings. The cathode giving 1·2 volts, corresponding to the state of pure aluminium, was taken out, dried with a cloth with nearly uniform pressure, exposed to air and was re-inserted in the cell. The nature and magnitude of voltages obtained depended upon time of exposure to air and are given in the accompanying table.

| Time of exposure | Succeeding voltages |
|---|---|
| 1 minute | 1·22 → 1·2 |
| 5 minutes | 1·23 → 1·2 |
| 15 ,, | 0·9 → 1·238 → 1·2 |
| 35 ,, | 0·85 → 1·247 → 1·2 |

The results clearly show the process of formation of the two layers and that the new layer is formed first, the oxide layer forming some time between 5 and 15 minutes of exposure.

If the plate on exposure was also washed with water and then dried with a cloth, the layers were formed much more quickly, which of course shows the deterrent action of the film of potassium hydroxide retained on the aluminium electrode in the absence of washing, in delaying the formation of the layer in virtue of its chemical activity.

In the present method, the lower layers are brought to the surface by the chemical destruction of the upper, which are then shown by their potentials.

I thank Profs. J. B. Seth and D. M. Bose for the experimental facilities provided.

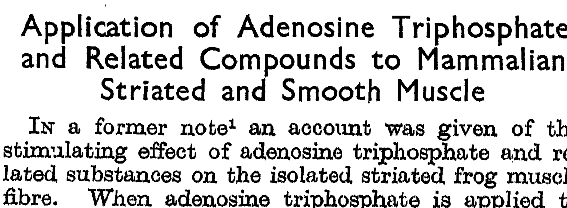
## Application of Adenosine Triphosphate and Related Compounds to Mammalian Striated and Smooth Muscle

IN a former note[1] an account was given of the stimulating effect of adenosine triphosphate and related substances on the isolated striated frog muscle fibre. When adenosine triphosphate is applied to *striated mammalian muscle* (m. tib. ant. of the decerebrated cat) by close arterial injection[2] in amounts of 0·05–0·53 mgm. per gm. muscle ($1·46–14·6 \times 10^{-6}$ mol./ml. = $0·1–1·0 \times 10^{-6}$ mol./gm. muscle) a rapid, tetanic contraction is released which is accompanied by interfering electrical activity (see accompanying record). Threshold dose and mechanical response are identical in non-curarized and curarized preparations, the effect of total curarization being insured by inexcitability of the sciatic nerve towards maximal stimuli and by insensitiveness of the muscle to intra-arterial injection of 50 μgm. acetylcholine. Intra-arterial injection of 5 μgm. acetylcholine after previous treatment of the non-curarized preparation with adenosine triphosphate releases a mechanical response with a considerably longer duration and higher tension than the same dose of acetylcholine does to a muscle without previous application of adenosine triphosphate.



MECHANICAL RESPONSE AND ACTION POTENTIALS OF M. TIBIALIS ANT. (CAT) AFTER CLOSE ARTERIAL INJECTION OF $0·6 \times 10^{-6}$ MOL. ADENOSINE TRIPHOSPHATE PER GM. MUSCLE.

Adenosine diphosphate ($1 \cdot 7$–$7 \cdot 0 \times 10^{-6}$ mol./ml. = $0 \cdot 12$–$0 \cdot 5 \times 10^{-6}$ mol./gm. muscle) likewise initiates tetanic contractions. Adenylic acid ($2 \cdot 6$–$8 \cdot 1 \times 10^{-6}$ mol./ml. = $0 \cdot 2$–$0 \cdot 6 \times 10^{-6}$ mol./gm. muscle) has stimulating effects on the non-curarized preparation, while the curarized muscle only reacts slightly or not at all. Inorganic sodium triphosphate ($2$–$12 \times 10^{-6}$ mol./ml. = $0 \cdot 15$–$0 \cdot 9 \times 10^{-6}$ mol./gm. muscle) and sodium pyrophosphate ($2 \cdot 5$–$17 \times 10^{-6}$ mol./gm. muscle) release tetanic contractions in curarized and non-curarized muscle, while inorganic sodium orthophosphate in amounts of $20 \times 10^{-6}$ mol./ml. ($= 1 \cdot 7 \times 10^{-6}$ mol./gm. muscle) is ineffective.

All chemical stimuli were applied iso-osmotically by replacing a corresponding amount of sodium chloride in the Thyrode solution with the substances in question; *p*H of the solution was 7·3.

When applied to *smooth muscle* (stomach and bladder of the cat by intra-arterial injection, and small intestines of the guinea pig by adding the substance to the surrounding Ringer bath) *only adenosine triphosphate initiates strong activity*. The threshold dose is approximately $0 \cdot 3 \times 10^{-6}$ mol./ml. ($= 0 \cdot 04 \times 10^{-6}$ mol./gm. muscle). The atropinized preparation which is insensitive to strong doses of acetylcholine still reacts to adenosine triphosphate. Adenosine diphosphate ($2 \cdot 5 \times 10^{-6}$ mol./ml. = $0 \cdot 35 \times 10^{-6}$ mol./gm. muscle), adenosine diphosphate plus orthophosphate ($5 \cdot 0 + 5 \cdot 0 \times 10^{-6}$ mol./ml. = $0 \cdot 7 + 0 \cdot 7 \times 10^{-6}$ mol./gm. muscle), adenylic acid ($2 \times 10^{-6}$ mol./ml. = $0 \cdot 26 \times 10^{-6}$ mol./gm. muscle), inorganic sodium pyrophosphate ($7 \times 10^{-6}$ mol./ml. = $1 \cdot 0 \times 10^{-6}$ mol./gm. muscle) and sodium orthophosphate ($14 \times 10^{-6}$ mol./ml. = $2 \cdot 0 \times 10^{-6}$ mol./gm. muscle) are completely ineffective on the stomach and the bladder of the cat, while pyrophosphate causes contractions in the small intestines of the guinea pig ($0 \cdot 22$–$0 \cdot 7 \times 10^{-6}$ mol./ml.). The effect of inorganic triphosphate ($6 \times 10^{-6}$ mol./ml. = $0 \cdot 83 \times 10^{-6}$ mol./gm. muscle) is either absent or slight. Thus the action of adenosine triphosphate on smooth muscle is highly specific and corresponds to its specific effect on the flow birefringence of purified myosin solutions[3].

These experiments support the view that adenosine triphosphate is an essential agent in the release of normal muscular contraction.

## Fortification of Pasteurized Cheese with Fish Liver Oils

A SYSTEMATIC search for natural foods that could be fortified with crude fish liver oils in order to supplement the vitamin A content of diets for native troops resulted in peanut-butter containing 5,000 I.U. of vitamin A per ounce being produced in large quantities. The peanut-butter masks the fishy flavours of the crudest fish liver oil, while the added vitamin has been demonstrated to be stable for six to nine months at high temperatures (85°–98° F.).

Continuing the above systematic search, the possibility of fortifying pasteurized cheese with crude fish liver oils has been investigated during the past year. Stonebass (*Polyprion americanus*) liver oil of 610,000 I.U. of vitamin A per gram, diluted with arachis oil to 80,000 I.U. of vitamin A per gram, stockfish (*Merlucius capensis*) liver oil of 9,370 I.U. of vitamin A per gram and Vaalhaai shark (*Galeorhinus canis*) liver oil of 26,800 I.U. of vitamin A per gram were added to cheese during the last stages of the pasteurizing process and thoroughly mixed. The degree of fortification aimed at in these experiments was 5,000 I.U. of vitamin A per ounce of cheese. The fortified pasteurized cheese was packed either in A 2½ cans and hermetically sealed or in standard ounce packages wrapped in tinfoil. The fortified cheese was stored at room temperatures and at constant temperatures of 85°–98° F.

Vitamin A in the cheese was determined by the Carr-Price reaction after ether extraction of the unsaponifiable fraction followed by removal of the ether. Losses of vitamin A during saponification, as indicated by Jones and Haines[1], suggest that the recovery values of 77–80 per cent of the vitamin added to the cheese are lower than the actual values. In no case could more than 90 per cent of the added vitamin A be recovered with the utmost precautions and refinements in the method of estimation. Some loss of vitamin A is thus expected in the process of fortification.

Losses of vitamin A during storage for 8–12 months at 85° F. proved to be less than 10 per cent. Cheese in ounce packages wrapped in tinfoil maintained its vitamin content just as well as cheese packed in hermetically sealed tins.

Only in the case when stockfish liver oil was added (amounting to 2 per cent of the cheese) could any suggestion of fishy flavour be detected, and then only by comparison with control samples.

The feasibility of fortifying pasteurized cheese with crude fish liver oils has thus been demonstrated. Crude liver oils of vitamin A potency ranging from 15,000 to 80,000 I.U. per gram would appear to be most satisfactory. The lower potency oils, such as stockfish liver oils, have to be added in such quantities that the consistency of the cheese is appreciably changed, although at no stage was any sign of fat separation from the emulsion visible.

## Role of Protozoa in the Aerobic Purification of Sewage

DURING recent years, there has been increasing amount of evidence regarding the importance of protozoa in the aerobic purification of sewage[1–4] and, more recently, some quantitative observations on protozoa in determining the condition of sludge and quality of effluent have been recorded[5–10]. The evidence so far obtained has, however, been only indirect, chiefly owing to the difficulty in separating

the protozoa from the associated bacteria. This has now been achieved and the object of this note is to show that the isolated protozoa can bring about practically all the changes associated with the purification. The part played by the bacteria is almost negligible.

We isolated the protozoa (Epistylis sp.) by first washing a part of the mucilaginous masses (adhering to the sides of the activation sludge tank) repeatedly on the centrifuge with the necessary precautions. A few living cells were then selected after microscopic examination. They were inoculated into vessels containing a sterilized, thin decoction of fæcal matter and vigorously aerated. After the sludge was built up, a fresh careful selection of cells was made. This operation was repeated a number of times until the associated bacteria (usually mechanically carried on the mucilage) were eliminated and the medium consisted exclusively of the active protozoa. The protozoa required fresh quantities of organic matter, together with liberal supplies of air, and so long as these were provided, there was no difficulty in maintaining them in an active condition.

That the isolated protozoa are at least as active as the normal activated sludge in the purification of sewage is shown by the following comparative study with sterilized raw sewage.

COMPOSITION OF THE EFFLUENT OBTAINED AFTER AERATION FOR 24 HOURS (IN PARTS PER 100,000).

| | Raw sewage at start (control) | Activated sludge | Protozoa (*Epistylis* sp.) | Mixed bacteria |
|---|---|---|---|---|
| Oxygen absorbed from permanganate in 3 min. | 1·87 | 0·26 | 0·21 | 1·23 |
| ,, in 4 hours | 4·16 | 0·51 | 0·41 | 3·95 |
| Free and saline ammonia | 2·46 | 0·62 | 0·57 | 1·98 |
| Albuminoid ammonia | 1·02 | 0·20 | 0·12 | 1·00 |

Further evidence is available to show that the conditions affecting the life and activity of the protozoa also affect the efficiency of the purification. There is practically no sludge formation or clarification when (*a*) the medium is selectively heated to about 50° C. so as to inactivate or kill the protozoa; (*b*) partial sterilizing agents (dyes such as methylene blue and acridine yellow which act selectively on protozoa) are introduced; (*c*) Chironomus larvæ which primarily destroy the protozoa are introduced; (*d*) fermenting yeasts, which are inimical to the protozoa, are added. The necessity for steady addition of fresh organic matter and also adequate aeration—both of which are essential to the protozoa—are too well known to require repetition.

Examination of sludges from activated sludge and other aerobic systems of treatment from various parts of India have revealed the presence and active functioning of protozoa wherever the purification is proceeding satisfactorily. If the protozoa are absent or found dead or encysted, there is no purification.

Starting from the investigations of Russell and Hutchinson on soil sickness and partial sterilization of soil[11], there has been a general tendency to regard protozoa as being inimical to the useful aerobic bacteria and aerobic processes in general. The earlier observations of Fowler and other workers[12-15] in the field of aerobic purification of sewage also pointed in the same direction. Evidence on the other side has, however, been steadily accumulating, so that with these and the conclusive evidence now reported, it can be stated that aerobic purification of sewage is essentially due to the protozoan activity. Bacteria play only a secondary part.

Further evidence on the phenomenon of flocculation by protozoa has already been adduced by other workers. Hardin[16] has recently demonstrated the flocculating activity on the part of the ubiquitous freshwater and soil flagellate, *Oikomonas termo* Kent. Watson[17] has recorded that the soil ciliate, *Balantiophorus minutus*, shows a similar ability to cause flocculation to that reported for *Oikomonas termo* and for Epistylis and Vorticella.

There are still some outstanding problems such as the mechanism of flocculation by protozoa and their exact role in the production of sludge having a high fertilizing value and in the related oxidation changes. These and related aspects are now being studied and will form the subjects of later communications.

## Pelage Change of the Stoat, *Mustela erminea* L.

IN 1942[1], I published an account of the change of pelage in the stoat, *Mustela erminea* L. The whitening of the coat in three out of five captive stoats was attributed to exposure to cold, although this factor did not seem to affect the commencement of the moult itself.

Prof. T. H. Bissonnette, who was working on the pelage change of weasels, very kindly sent me his then unpublished data with many valuable suggestions. He considered it possible that the change to white was only an indirect result of the cold, produced by the animal's loss of activity and consequent curtailment of its own daylight by longer periods spent in the sleeping boxes. He has since published[2] his own experiments with Bonaparte's weasel (*M. cicognanii cicognanii* Bonaparte) and the New York weasel (*M. frenata noveboracensis* (Emmons) ). In the case of the former he shows conclusively that the change of pelage, both with regard to moult and whitening, could be controlled by manipulation of the light-cycle. In the latter species the moult was similarly controlled; but the colour change involved only a change to light brown and not to white. Farther north, in the wild, this weasel (at least the female) turns white in winter.

The War has unfortunately interfered with my own experiments, but the following observations seem worth recording.

In 1942[1], I stated that "captive stoats have two moults". Since then I have found two specimens which moulted twice during the winter. It is inadvisable to handle these animals frequently as some risk of injury to themselves is always involved. It is, therefore, very easy to overlook the first winter (or autumn) moult, which is from brown to brown, and indeed it seems probable that this oversight has occurred where other specimens are concerned. I had previously noted[1] that in my captive stoats the white pelage was carried for three to four months only, but that judging from museum skins, wild stoats in Scotland remained white for much longer periods. In the case of the former a colour change was involved in only one winter pelage; but it is possible that two successive moults may be white under the conditions prevailing in Scotland. Bissonnette found that his captive Bonaparte weasels could be induced to moult from white to white.

Although considerable variation occurs between individuals, and also from year to year in the same specimen, the order of the moult is similar to that described by Bissonnette for both species of weasels. Winter moults begin on the underneath of the belly and sweep up the legs, tail (distal portion first) and sides of the body. The top of the head and a narrow line down the neck and centre of the back are the last portions to turn white. In the spring moults the process is reversed, and the brown hairs grow in first on the head and along the middle of the back. The tip of the tail, of course, remains black throughout.

Even if the winter moult does not involve whitening, the brown coat is slightly lighter in colour than the summer coat. The hairs on the belly are also less strongly tinged with yellow, although not pure white.

Experimental reduction of daylight was carried out with five captive stoats. It was found that by sudden or gradual shortening of the hours of daylight, additional moults could be induced in the spring and summer, but none of these moults involved a colour change. In one male stoat only, a few white hairs appeared on the feet and legs. This specimen had never previously changed colour. Afterwards it retained these white hairs throughout all moults over a period of two years.

Stoats which were subjected to gradual but drastic light reductions during the critical periods of the winter moults also did not change colour. One of the stoats in question had made a partial change to white in each of the two previous winters when exposed, during a period of sixty-three days, to thirty-four and forty-four days of temperatures below 32° F. However, this stoat did not change colour at all under warmer conditions, despite curtailment of the hours of daylight. It was subjected to only twelve days of temperatures below 32° F. The increased hours of darkness commenced on September 21 and on December 21 culminated in a three-week period, in which five hours of daylight alternated with thirty-six hours of darkness.

It will thus be seen that with regard to whitening of the pelage, *M. erminea* is far less susceptible than *M. cicognanii* to the effect of light reduction alone. This factor apparently plays a subsidiary part in the colour change of the British species. It does seem likely, however, as Prof. Bissonnette suggests, that reduction of temperature involves a change of habit which brings about a natural reduction of the light cycle and perhaps loss of activity, and that these factors play a complementary role in producing both moult and colour change. It would be extremely interesting to know if the New York weasel (*M. frenata*) could be induced to whiten if subjected to low temperatures in addition to reduced hours of daylight which induce only a moult to paler brown. It seems clear that the response to the different factors governing pelage changes varies greatly, not only from individual to individual and at different times of the individual's life, but also from species to species.

## An Unusual Host for a Polypore

IN December 1943 through the kindness of Dr. K. P. Biswas, superintendent of the Lloyd Botanical Gardens of Darjeeling, I obtained a few specimens of green leaflets of a Macrozamia sp. from the Darjeeling garden bearing tiny fructifications of *Polystictus sanguineus* (Linn.) May. on their back surface (see accompanying illustration). Sections of the fructifications showed normal basidia and white and oval spores (4–6 × 3–4 mic.) of *P. sanguineus*. In sections of leaflets under the microscope partial disintegration of chloroplastids at places and formation of tannin drops were detected though the leaflets were quite green to the naked eye.

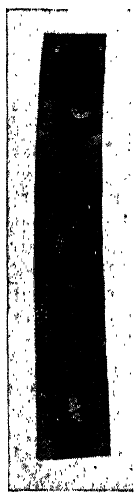

FIG. 1. FRUCTIFICATION OF *P. sanguineus*.

So far, I have not come across any mention of a polypore fruiting on green leaves of higher plants—an apparent parasitic habit; by correspondence (March 9, 1944) with Dr. L. O. Overholts of the Pennsylvania State College I learn that he also has no such experience. Thus, this may be recorded as the smallest polypore yet known.

## The Pisiform Bone

PROF. H. A. HARRIS's[1] rediscovery of the secondary centre of ossification in the pisiform confirms the work of Retterer[2], who found it in cat, dog and rabbit, and Sieglbauer[3], who found it in chimpanzee, gorilla, Tarsius, Stenops and Macacus. But his conclusions from its "hitherto unsuspected existence" are scarcely justifiable, for there is no reason for believing that secondary centres are a prerogative of one type of skeletal element. His letter does raise the question of what criteria can be used to determine whether a bone is a sesamoid.

Sesamoids appear where tendons of muscles turn over bony prominences, and have one surface cartilage-covered to glide over the prominence, separated by a synovial cavity, while the other

surface is embedded in the tendon. The synovial cavity is usually an extension of the cavity of the neighbouring joint, but may be (for example, peroneus longus) a part of a synovial bursa. Sesamoids appear first as mesenchymal condensations of the tissues between the developing tendons and prominences[4]; the deeper parts are always developed in cartilage, but the part embedded in the muscle may be formed of calcified tendon substance later replaced by lamellar bone. Historically, sesamoids are unknown in all carboniferous and Permian animals, and have never been developed in the lines leading to the modern urodeles, turtles, crocodiles or Sphenodon, but have been developed by independent evolution in several other groups[5].

The essential factor for the development of a sesamoid is the pressure of a bony prominence, so that the tendon is exposed to lateral pressure at the same time as it is stretched. Some sesamoids may increase the leverage of muscles, but their removal does not greatly affect muscular power. Probably they are concerned rather with the maintenance of the vascular supply of the tendon in the region where the blood vessels would otherwise be liable to prolonged occlusion by lateral pressure. In this they are analogous to the ossified tendons found in several dinosaurs, birds and kangaroos[6].

Sesamoids can usually be recognized from their positions and relationships, but sometimes special criteria must be used. The pisiform does not articulate with a single bony prominence in most animals, but fills the gap between the ulna and ulnare; and even when, with increasing freedom of ulnar deviation at the wrist it comes to articulate with the ulnare (triquetral) alone, it does not glide over this bone as a sesamoid should, and its synovial cavity is a separate formation. It is, as many authors have indicated, constantly present in all early reptiles and is indicated in the amphibian Eryops and so cannot be a sesamoid[7,8]. The patella, on the other hand, to take another bone the morphology of which has been questioned, is a sesamoid because it has the typical structure, position and relationships, it is exposed to pressure as it turns over the lower end of the femur, and it is not developed in primitive tetrapods. Harris's criterion, the presence of a secondary centre, already discussed at length by Sieglbauer[3], is of doubtful value in recent forms, and is useless in early forms as no secondary centres appear before the Triassic.

IN a recent letter in *Nature*, Prof. Harris[1] gave radiological evidence for the appearance of a separate epiphysial centre in the pisiform bone of sub-human primates. In view of the considerable theoretical importance which he attached to this finding, further observations have been made in this Department. A number of female Rhesus monkeys of accurately known age were available for X-ray study. The result of this investigation has been a smooth and continuous record of the developing pisiform bone in the macaque monkey from birth to maturity.

Examination of the individual films shows that in the female macaque the centre for the body of the pisiform is already present at birth. It is well marked at the age of four months and has attained almost adult size and shape at 16½ months, at which age, however, there is no trace yet of a secondary, epiphysial centre. But the latter is clearly present at the 20½ months, 22½ months stage and still later, at 36 months, although by that time the thickness of the epiphysial cartilage appears much reduced. At the age of six years the Rhesus monkey no longer possesses a radiologically demonstrable epiphysis, and fusion must have taken place during the intervening time.

Thus the existence of a separate epiphysial centre in the pisiform of macaques has been amply confirmed. In addition, the 'life-span' of this centre has now been more clearly defined for, as shown above, it makes its first appearance between the ages of 16½ and 20½ months and fuses with the main centre between three and six years.

Many workers in the past have studied the morphological significance of the pisiform bone, but the literature shows that no uniformity of opinion has yet been reached. The view that it corresponds either to the whole of the os calcis or only to its tubercular part has been expressed before, mainly by the older school of comparative anatomists such as Lavocat[2], Albrecht[3], Baur[4], von Bardeleben[5] and, more specifically, by Ed. Retterer[6]. This worker, after demonstrating the existence of two separate bony centres for the pisiform of the rabbit, cat and dog, concluded in 1898: "Ce mode de développement et la texture du pisiforme adulte m'ont porté à considérer ce segment comme un os long ou au moins comme l'homologue du calcanéum".

Now that the primates can be added to the list of species possessing a separate bony epiphysis, this view seems to be much strengthened.

I am most indebted to my two former colleagues for pointing out the previous descriptions of the epiphysis in the pisiform bone by Retterer and Sieglbauer. I had previously consulted several anatomists on this point, but without success. *Magna est veritas* . . .

The additional radiographic evidence by my former student Eckstein as to the time of appearance and union of this epiphysial ossification centre in the Rhesus monkey is of great interest. The pisiform, so often dismissed as a minisculum, may yet be of inordinate morphological significance. Haines and Hughes have looked in the library; Eckstein has looked in the monkey!

H. A. HARRIS.

# A CRYSTALLINE SERUM MUCO-PROTEIN WITH HIGH CHOLINE-ESTERASE ACTIVITY

By DR. R. BADER, DR. F. SCHÜTZ and DR. M. STACEY

Medical School and the Chemistry Department, University of Birmingham

THROUGH the work of Dale and Loewi and their schools, acetylcholine is recognized as the effector substance of the cholinergic system and is known to be decomposed by an enzyme present in serum and tissues[1] which is designated 'choline-esterase'[2]. It appears to be an undecided question whether choline-esterases from different tissues, such as blood and brain, are identical.

Some recent work[3,4] made it desirable to have a highly purified preparation of choline-esterase available for experimental and perhaps clinical investigations. A method was therefore devised whereby good yields of very active and frequently crystalline preparations can consistently be obtained. In our hands, Stedman's method[5] gave somewhat irregular results and the products were invariably contaminated with serum albumin. One of the essential features of our method, briefly outlined below, involves adsorption on foam, a technique[6,7] which at certain stages gives a sharp separation of closely related substances. The main stages in the purification were as follow.

(*a*) Solid ammonium sulphate (250 gm./litre) was added to fresh horse serum, kindly provided by Dr. J. W. Trevan, director of the Wellcome Physiological Research Laboratories, and the relatively inert precipitate was rejected. A further 150 gm. of ammonium sulphate were added for each litre of the mother liquor and the precipitate was dissolved in water. From this solution the lipoids were extracted by precipitating the proteins at $-15°$ C. according to Hewitt's modification[8] of Hardy and Gardiner's method. The ether-washed precipitate was then extracted in a Soxhlet for at least forty-eight hours with ether containing metallic sodium, both of which were once renewed. The extracted material (a powder) was dried in a vacuum. It was then made into a paste with water and dialysed at 0° for several days against frequent changes of distilled water saturated with chloroform. A precipitate of inert insoluble material was then separated (centrifuge). The activity of the solution was twice that of the original serum.

(*b*) The solution was then frozen (twice) at $-72°$. From the thawed solution considerable amounts of inactive material were removed by adsorption with specially prepared fuller's earth at $+2°$ C. The adsorption, which required several days for completion, was controlled by frequently estimating the activity per dry weight of the solution. The fuller's earth was removed (centrifuge) and the yellow, slightly turbid solution had an activity per dry weight of about 4–6 times that of the original serum.

(*c*) The solution was adjusted to *p*H 8 (caustic soda) and foamed[6,7] at 0°. In this process a slow stream of nitrogen was bubbled through the liquid and the rising foam separated from the bulk of the solution. When foamed at an acid *p*H, much of the choline-esterase was adsorbed on the foam, but its purification was unsatisfactory. If foamed at an alkaline *p*H it remained almost entirely in the liquid while a considerable quantity of inactive material passed over in the foam. The foaming was continued until the residual liquid did not contain any heat-coagulable substance (100°) and until the foam time[9] was reduced to about a twentieth of that of the original solution. This required approximately three days, and usually up to 15 per cent of the original liquid was removed in the foam. The residual liquid now had an activity per dry weight 8–16 times that of the original serum. It had a *p*H of 8·5, while the liquid removed as foam had a *p*H of 5.

(*d*) To the clear colourless residual liquid solid ammonium sulphate (350 gm./litre) was added and the solution kept overnight at 0° (*p*H 6·0). The precipitate was rejected and a further amount of solid ammonium sulphate (100 gm./litre) added to give a precipitate, *A*. If instead of adding solid ammonium sulphate to the solution, the latter was dialysed against an aqueous ammonium sulphate solution (450 gm./litre), a frequently crystalline precipitate (Fig. 1) was obtained. These crystals, dissolved in water and dialysed against water, showed an activity (per dry weight) of approximately 20 times that of the original serum. They had essentially the properties of the preparations described below, but optimal conditions for their separation in quantity have not yet been worked out. The precipitate *A* was further purified by reprecipitation and thorough dialysis against water. When samples of this product were dissolved in water, adjusted to either *p*H 3 or *p*H 8 and evaporated cautiously at room temperature, a partially crystalline mass was formed. The crystals obtained at *p*H 8 always had the form shown in Fig. 2, and those at *p*H 3 were less well defined though both had an activity (per dry weight) of 20–25 times (and sometimes even higher) that of the original serum. No crystalline material could be obtained in the *p*H range of 3–8, and the best conditions for crystallization have not yet been worked out.

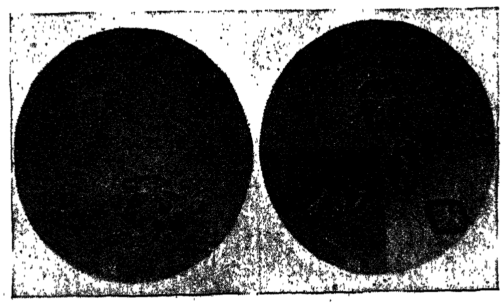

FIG. 1. FIG. 2.

Without previous foaming similar precipitations did not give preparations free from heat-coagulable substances or of such high activity. A typical preparation which in the dry state remained active over a long period was free from phosphorus and sulphur, showed $[\alpha]_D - 35°$ in water, nitrogen 12·4 per cent and had the properties of a mucoprotein[10]. Freshly prepared solutions contained no heat-coagulable substance (at *p*H 5), although precipitates were obtained with the following reagents: 50 per cent ammonium sulphate, 10 per cent trichloracetic acid, Esbach's picric acid, basic lead acetate, phosphotungstic acid. Sulphosalicylic acid and 1 per cent trichloracetic acid gave a turbidity only. The xanthoproteic (colour, but no precipitate), biuret, Millon, Sakaguchi,

glyoxylic and other tryptophane tests were positive. In freshly prepared samples the ninhydrin test was negative, but samples which had been kept in solution at room temperature for several days and which rapidly lost activity readily gave this test. Samples hydrolysed by either acid or alkali gave a vivid colour with ninhydrin (deep purple slowly fading to cherry red). The Molisch test for carbohydrate was strongly positive and was typical of that of 'bound' carbohydrate, in which the Molisch colour develops relatively slowly but remains stable for periods up to several hours. After hydrolysis, products were obtained which reduced Fehling's solution weakly and gave a positive Elson-Morgan test for amino-sugar. X-ray powder photographs, kindly taken by Drs. F. J. Llewellyn and A. D. Booth of our X-ray department, of all crystalline samples showed a number of diffuse rings in which there was no evidence of a highly ordered structure. The photographs were similar to those of crystalline pepsin taken at the same time and to those of some crystalline 'globular' proteins as described by Astbury[11].

The yield of choline-esterase calculated on the amounts estimated in the original serum gave surprisingly high figures, usually between 60 and 100 per cent but often much higher. We interpret this result as being due to the existence in serum of one or more powerful inhibitors which were removed during the purification process. The figures representing activities are usually taken as an indication of the degree of purification. We prefer, however, to postpone the interpretation of the significance of these figures until further information is available on the above-mentioned inhibitor, and on possible activators removed during the purification process.

We do not attempt at this stage to claim that the crystalline mucoprotein is indeed the pure enzyme, but the absence in the preparation of heat-coagulable albumins and globulins, the steady and regular increase in activity per dry weight during the process of purification and the initial negative ninhydrin test make it appear probable that the choline-esterase activity is intimately connected with the mucoprotein. It appears, moreover, to be the first mucoprotein which has been separated from the albumins and globulins of serum by a method which avoids the use of substances (such as alcohol) or procedures (for example, heat) known to denature or to destroy enzymes, in particular choline-esterase. Mucoproteins, having varying amounts of carbohydrate residue, have frequently been prepared from serum after removal of albumins and globulins by coagulation methods involving the use of heat and alcohol (for literature see Rimington[12]). Our preparation had some properties similar to those of seromucoid[12], but the method of preparing this mucoprotein would, of course, destroy choline-esterase activity.

Since this work was completed, there has appeared a paper[13] on "pseudo-choline-esterase" which the author has isolated in 5 per cent yield from horse serum and which is claimed to have an activity 5,000 times that of serum. The reason for the big discrepancy between this apparent high activity and our own is not immediately clear. In view of the fact that despite experimental losses our yields are so consistently high, we are inclined to the view that the divergence lies in the method[14] of assay of the enzymic activity; particularly since we have preferred not to use any enzyme stabilizer (gum acacia) and have worked with lower substrate concentrations.

## UNIVERSITY DEVELOPMENTS IN GREAT BRITAIN

THE Conference on University Developments, arranged by the Association of University Teachers on June 2, at which representatives of twenty universities and colleges were present, considered three of the main topics of the Report on University Developments adopted by the Council of the Association in December and published in the *Universities' Review* of May. First, Prof. Ray Pascal opened a discussion on university entrance requirements, maintenance grants, curricula and appointments boards. Emphasizing that the consideration of such matters pertaining to the teaching functions of universities could not be conducted without reference to other functions such as research, Prof. Pascal directed attention to two main objects behind the proposals of the Report: the development of people who will make a useful contribution to society in whatever profession they may choose; and the development of individual personality of people able to "distinguish, choose and judge". Too often we have aimed alternately at one or the other. The Council of the Association does not believe that this is either good or necessary. We need not only really efficient experts but also efficiency in the widest sense applied to society as a whole, calling for broad knowledge and understanding, for initiative, adaptability and personality. The proposals to replace the scholarship system by one of maintenance grants, to change the character of the entrance requirements and to adapt the curriculum are all intimately related, and Prof. Pascal noted that related views have been expressed in the report of the Education Committee of the Federation of British Industries.

In regard to maintenance grants, the Association is concerned not only that the best should be provided for, but also that a great number of average good students should be forthcoming. Many scholarships awarded in recent times have denoted not special academic merit, but a recognition of fitness to study, and a change in name to correspond with this fact is proposed and an increase of 50 per cent in such grants—a provisional figure which can be soon attained without extensive new building and for which reserves of university teachers can be found. In regard to entrance requirements, the Association's proposals to correct the bias towards premature specialization centre in the transformation of the higher school certificate into a school-leaving examination in about six subjects, and useful for all leaving purposes, not merely for the universities. For university entrance, a further examination is needed

in a smaller number of subjects, but so framed as to prevent exclusive concern with two or three subjects over a long period. Here agreement and co-operation between universities rather than uniformity is required.

The Association's criticism of degree courses is that too many students specialize who are not fitted for the most advanced specialist work, and that the best students need a broader basis. It proposes a common course in the first year or two, followed by full specialization for those suited by ability and bent, and extension of the normal university course to four years once the post-war rush is over, with a much larger entry for the general degree course. Again, in regard to appointment boards, these should be bodies on which university teachers meet employing bodies to exchange information and to consult together on the relations between education and employment.

Dr. D. R. Pye, opening a discussion on research, using the word in its widest sense as giving vitality to teaching, pointed out that while it cannot be expected that all members of a university staff will remain productive in research, much good would result from closer association between universities and the research staffs both in Government establishments and in industry, and he referred to the value of university lectures by research workers on their special subjects as a stimulus to post-graduate research groups in the universities. Also it must be possible for the universities to pay salaries which are adequate to retain the men who are capable of effective research and of training recruits in research; the number of such men must be sufficient to prevent them from being overburdened with teaching.

The closer association of the universities with industry presents special difficulties in the engineering faculties. Here, except in the borderland of physics and engineering, and especially towards the physical side, effective research is difficult to arrange at the universities, and it will always be difficult for the university work to keep in touch with changing technique. Accordingly, Dr. Pye welcomed the encouragement of local contacts with industry. He deprecated too close inquiry as to whether research is pure or applied: freedom in planning and in execution are pre-requisites for research which is worth while, but a fairly definite goal is no bad thing for the majority.

Prof. S. Brodetsky, opening the third discussion, on salaries, superannuation and representation of academic staff and academic council of the universities, said that a considerable increase in the staffs of universities is clearly necessary as well as a new scale of salaries, but he appeared to be opposed to the establishment of further research fellowships as recommended in the Association's Report. In regard to the new scale of salaries suggested, he emphasized the desirability of discontinuing the so-called "Grade IV" appointments, and, secondly, that lecturers should reach a reasonable salary by about the age of forty. The Report proposes a salary of £800 to be reached by annual increments, following a probationary period, at about that age. Higher appointments, such as Grade I lecturers or readers, should similarly rise to £1,100, non-professorial heads of departments to £1,300, and for professors a basic salary of £1,500 is suggested. With regard to superannuation, a special Government grant is called for to put on a reasonable level members of university staffs of long service.

Prof. Brodetsky also directed attention to the importance of university teachers taking a proper place in the administration of the universities, and to the recommendations in the Association's Report that university councils should include a fair representation of the university staff, both professorial and non-professorial. Each university should have permanent academic committees dealing with the question of development and other problems, while in connexion with regional universities special thought must be given to the place that graduates should occupy in their development and government. Finally, referring to the relations between the universities, he explained the reasons why the Association's Report recommended the establishment of an academic council of the universities to facilitate consultation and the work both of the University Grants Committee and the informal Vice-Chancellors' Committee.

The summer meeting of the Central Council of the Association of University Teachers took place on June 9 and 10 at the University of Birmingham. Forty-five members were present, representing the local associations in the various university institutions of England and Wales. The action of the University of Birmingham in making a gift of £100 to the University Books for China Fund, following an appeal made by Prof. E. R. Dodds, of the University of Oxford, who had recently returned from a visit to Chinese universities, was brought to the notice of members in the hope that other university institutions might feel able to help in a similar manner. A report was made regarding the conference of representatives of university governing bodies and members of the executive committee of the Association which took place on June 2 (see above). A Conference Committee was appointed to arrange for a series of conferences with, among others, school teachers and professional, technical and industrial organizations, the National Union of Students, etc., to consider specific problems arising out of the report. Copies of a booklet on "Health and the Student", issued by the National Union of Students, were before the meeting and, after consideration, it was agreed that it was desirable to support the efforts of the Union in this direction, and to recommend local branches to raise the whole question of student health (including medical care and welfare, living conditions and recreative facilities) with their governing bodies. The election of officers for the session 1944–45 was proceeded with, Prof. Roy Pascal of the University of Birmingham being appointed president.

## A FLATWORM PARASITE OF FRESHWATER TROUT

INVESTIGATING the cause of the deaths of practically 100 per cent of the freshwater trout in an open storage reservoir in South Wales in 1942, J. B. Duguid and Edith M. Sheppard (*J. Path. and Bact.*, **56**, 73; 1944) found that they were due to general peritonitis caused by the plerocercoids of a tapeworm belonging to the family Diphyllobothridæ. Hundreds of these flatworms, 1–10 cm. long, were found burrowing in the peritoneal tissues. The sticklebacks (*Gasterosteus aculeatus*) in the same reservoir were also infested.

The reservoir supplies domestic water and stands next to a suburban area, and is fed with filtered and chlorinated water conveyed by a closed pipe from reservoirs 25 miles away. A second smaller reservoir, separated only by a narrow embankment from the one in which the fish died, is used for industrial purposes and is fed from local streams. Both are stocked with trout and have been open to anglers for years. Apparently there have been no earlier outbreaks of disease in this reservoir. Many trout from other sources, including the supply reservoir 25 miles distant, were examined, but the cestode was not found in them, until, in March 1943, it was found in trout from the second smaller reservoir.

When the plerocercoids were fed to laboratory rats and to one dog, they developed into adult worms which resembled *Diphyllobothrium latum*, the 'broad tapeworm' of man. On the other hand, when they were implanted into the subcutaneous tissues and peritoneal cavities of rats, they did not multiply, but were encapsuled by fibrous tissue, remaining alive for three weeks. Identification of the species of the family Diphyllobothridæ is difficult, because only one stage in the life-histories of so many of them is known. The identity of the species found in these trout with *D. latum* of man has not yet been fully established. The adult, the egg, the coracidium and procercoid seem to correspond with those of *D. latum*, but the plerocercoids do not; they seem to correspond with the descriptions given of *Dibothrium cordiceps*, which caused epidemics in trout in one of the Yellowstone Park Lakes. Similar epidemics have occurred in Elk Lake, Oregon and in California. Some helminthologists regard *D. cordiceps* as being identical with *D. latum*; others do not.

The authors' further work on the identity of this parasite will be awaited with interest, because *D. latum* is recorded in the British Isles only from the west of Ireland. To this record, Duguid and Sheppard add the Shetland Islands, where it is, they conclude from material supplied to them by Dr. Peterson of Yell, endemic among the freshwater trout of certain areas. *D. latum* is described as being cosmopolitan by some authorities, but the most important foci of it are all around the Baltic Sea, some of the Lakes of Switzerland and Italy, Bavaria, Hungary, the Danube delta, Poland and Rumania; it is also common in Turkestan and parts of Siberia and Japan, and foci are known in Africa. Its definitive hosts, apart from man, include the dog, cat, pig and various aquatic and terrestrial carnivores. It requires two intermediate hosts, a freshwater copepod and a freshwater fish (perch, pike, salmon trout, etc.). The Cyclopidæ *Diaptomus gracilis* and *Cyclops strenuus* are commonly the crustacean hosts, and Duguid and Sheppard describe the life history of the South Wales species in these two copepods. They had not, at the time of writing, infested fish by feeding them with infested copepods. Nor could they explain how the parasite got into this carefully protected reservoir. They found little evidence that birds (for example, the gull) brought it there; it seemed more likely that a small mammal was the carrier. One Belgian soldier, who was later found to be a carrier of *D. latum*, had camped in the neighbourhood.

Commenting on this paper, *The Lancet* (April 8, p. 475) points out that *D. latum* has been introduced by immigrants into the United States, and suggests the possibility that it may have been brought to Great Britain by refugees from Norway or Poland.

# RECONSTRUCTION IN THE CIVIL SERVICE

In the debate which took place in the House of Commons on January 28, 1943, on the sixteenth report for the session 1941–42 of the Select Committee on National Expenditure, on "Organization and Control of the Civil Service", the Chancellor of the Exchequer, Sir Kingsley Wood, welcoming the general tenor of the Committee's observations on the establishment of a Civil Service staff college, stated that he proposed to start at once an investigation into the general question of the training of Civil servants, including that of the establishment of a staff college, its form and character. A committee was appointed for this purpose in February 1943 under the chairmanship of the Financial Secretary to the Treasury, the Right Hon. Ralph Assheton, and its report was duly presented to Parliament in May last.

In the meantime, the importance of the question of training of Civil servants has steadily become more widely recognized. In the attention which has been given to the machinery of government by such bodies as Political and Economic Planning, the importance of men as well as the right methods has been repeatedly emphasized. The same question has been to the fore in current discussions on the reform of the Foreign Service and on proposals for a civil or economic general staff. Already education for the public services has been considered in a special report of the British Association Committee on Post-War University Education, while further discussion of the question has been stimulated not only by the White Paper on Education but also by subsequent papers on health services and employment. The proposals in the latter paper for a strong central economic staff were rightly stressed by the present Chancellor of the Exchequer and were warmly welcomed by many members of Parliament in the debate.

It has, in fact, become increasingly clear that in the successful execution of whatever plans we may make for our post-war reconstruction, much will depend on the calibre of the men to whom their execution must perforce be entrusted. It is, of course, above all in the technical field that complexities multiply; and the larger the part that science has to play in the ordering of our affairs, the greater the need for decisions and policy to be based impartially on scientifically ascertained facts. If the State is to discharge effectively its more active duties of planning and supervision, the more imperative is the need for the Civil Service to be trained for the job it has to do. The Assheton Report does not, it is true, pursue in detail the training of the professional and technical grades. That is not the special issue at present, except in so far as it is bound up with the general question of technical education in relation to industrial efficiency under the plans for educational reconstruction. What is at issue is that members of these classes should, as was most emphatically stated in more than one recent debate in Parliament, have fuller opportunities of transfer to the administrative class, when they show themselves to possess administrative ability. There must be much

more adequate encouragement of a process of such direct value to the machinery of government, apart altogether from its indirect effect, through the higher status and wider prospects given to the scientific worker, in attracting to the service of the State a freer supply of men of outstanding scientific as well as administrative ability.

For this reason, as a preparatory step, recruits to the professional and technical classes might, as the Report suggests, usefully share in the reception arrangements and background training which are recommended for all Civil servants, so that they may be seized of the functions of the government machine generally and the procedure of their own departments in particular. Again, members of these grades, who are in certain respects analogous with the administrative class and with the higher levels of the executive class, should also be given, where appropriate, the same opportunities for acquiring wider experience by the study of outside methods and by other measures such as are recommended by the Report. Training, it is observed, cannot be considered in isolation; such matters as recruitment, allocation, probation, transfer and promotion are all involved. All indeed are considered by the Report in so far as they are factors in determining the character and extent of training, and the efficient performance of those functions which must fall to the lot of a Civil servant more and more concerned with the affairs of the community and acting as the servant of the State in numerous ways which involve contact between the government and the individual citizen.

The Report itself is in two parts. The first deals with general considerations and principles; the second indicates some of the ways in which they can be applied to the various grades that have come under review. Looking first at general principles, the Report recommends that the Treasury should exercise general control over training and should appoint a director of training and education. Within each department there should be a planned training scheme under the general control of the head of the department, with at least a part-time departmental training officer. The National Whitley Council should be associated with general training policy, and departments should invite the co-operation of staff representatives in working out departmental schemes. Not only should great care be taken in the selection of teachers, but also attention should be paid to the surroundings in which people work.

The reasons for these recommendations are cogently set forth in the Report. There can be no dissent from the Committee's view that training schemes will not prosper unless responsibility for their success is firmly placed on some individual. The Treasury's responsibilities for establishment work and the new development of the Organization and Methods Division make it logical that general responsibility for training should also be with the Treasury. Again, the element of staff co-operation is emphasized in a way which represents a break with tradition and a look forward to that closer integration of the service with the community, which is just as important as that of industry with the community, in order that the needs of to-morrow may be served. The emphasis on personality in teaching and on environment equally betoken a forward-looking mind. Indeed, it cannot be too clearly emphasized that the Report is largely breaking new ground and that its recommendations are experimental; that, far more than shortcomings or defects of the past laid bare in the Report, is what matters, and what should ensure it a sympathetic reception and patient and full discussion.

The objects of the training to be given could, in fact, scarcely be better put than in this Report. Public confidence is essential if the Civil Service, however admirably trained for its more positive functions, is to discharge its new duties effectively. We may take for granted that training should endeavour to produce a Civil servant whose precision and clarity in the transaction of business are accepted. Equally we have no right to expect that the Civil servant will be attuned to the tasks he is called upon to perform in a changing world, or that he will be able continuously and boldly to adjust his outlook and methods to meet the new needs, unless we are prepared to support him with sympathy and understanding, and temper criticism with discernment.

It might well be observed in passing that the stress laid in this Report on the human aspect among the objects of training should do much to promote such understanding of 'the man at the other end', and a real integration of the Civil Service with the community it seeks to serve. Measures which prevent the Civil servant from becoming mechanized by making him aware of the wider setting of his work, by training him, not solely for the job which lies immediately to hand, but also to fit him for other duties and to develop, where appropriate, his capacity for higher work and greater responsibilities, all assist to that end, as does the attention to staff morale which is emphasized. In such matters as these, in its frank recognition of the human problem presented by routine work and mechanization, the Report is pointing to problems which industry, too, must face in increasing measure. They are indeed already being faced by many progressive firms, as well as by the joint production councils, but they must receive far greater and wider attention.

Returning to the general principles recommended in the Report, there is emphasis on a real period of probation which would facilitate the early elimination of misfits. Next, there should be a routine of training for all entrants under a responsible officer. Mobility in the early years of service, both from branch to branch and from headquarters to out-stations, and easier transfer from one department to another are also recommended. Clearly much will depend on the careful selection of supervisors and their training in the principles of supervision, as well as on the ability of establishment officers, who should study staff management and office organization.

Despite many unexceptionable recommendations, much of the interest of scientific workers in this general part of the Report centres in the considerations which lead the Committee to reject the proposal that the Government should associate itself with the establishment of a national administrative staff

college, though if such a college is set up some Civil servants might attend experimentally. In the first place, the Committee concludes that little or no centralized or institutional training is needed for the clerical, executive and professional grades: the necessary training is most readily and effectively given by departments. For the administrative officer, however, the Committee sees a real need for a central organization to give the appropriate teaching about the background and methods of Civil Service administration to recruits to this grade of all departments. Further, such an organization should serve a useful purpose in bringing together administrators at a later stage for discussion and investigation of common problems.

The Committee thus visualizes training primarily for new entrants and not, as in the staff colleges of the Armed Forces, for those selected as suitable for promotion after some years of experience. Again, while heartily in favour of encouraging contact between Civil servants and workers in other departments of life, especially in commerce and industry, the Committee does not think that these contacts can best be secured through a common course of instruction in administration. Both the lessons and the illustrative matter of Civil Service administration are regarded as too specialized to be made useful in a college of the kind suggested to the Committee. Further, from the evidence, the Committee thinks that there is a danger that such an institution would end by becoming a commercial college concerned with office methods, and that a real opportunity of assisting the Civil Service administrator to a rapid comprehension of the nature of his problems and of the lines of thought and action he should follow would be lost if such training were merged in a generalized administrative course for both business and the Services.

The Committee's own proposals are elaborated more fully in Part 2 of the Report, in considering the post-entry training of the administrative class. Here more than anywhere, the Report breaks new ground, and it is satisfactory to note that there is no suggestion that Civil servants should not receive their training in the universities or other institutions of similar rank in company with men and women destined for other careers. We can find nothing in the Report to warrant the anxiety expressed last year in these columns (*Nature*, **151**, 512; 1943) that entry will be unduly restricted or the functions of the universities be adversely affected. It may, indeed, be argued that something more of the principles of administration might well be taught prior to entry to the service than the Committee is inclined to admit; but incontestably there is much training in internal methods and background that has hitherto not been given at all, or at best unsystematically, and which can only be given effectively after entry to the service.

The section of the Report in which the Committee's own ideas are outlined deserves careful attention, for if some of the proposals are admittedly experimental, the Report reveals an urgent need for action. Moreover, if as it appears the Committee has taken rather too narrow a view of its scope and under-estimated the potentialities of the staff college idea, it is to public discussion that we must look for the corrective in the first instance.

As regards the administrative cadet, the Committee suggests a course of two to three months requiring an average attendance of about two days a week, the object of the course being to shorten the process by which the recruit forms his own administrative standards, and to inculcate from the beginning of his service a professional approach. As set forth in the Report, much of the syllabus appears to be of wider validity than the Committee is disposed to admit. The reference to training in methods of preparing and presenting statistics, and the logical principles underlying their interpretation, is welcome, and the Committee is on firm ground in urging that the close relation of such a course to a Civil servant's particular job might well increase its vitality and value. Moreover, from the comparatively modest beginnings outlined, the Committee visualizes the development of a centre which could serve as a clearing-house of ideas for Civil Service administrators and a repository of schemes, successful and unsuccessful, which have been tried out in practice. In fact, after rejecting the idea of a staff college, the Committee sees such a centre organizing refresher courses in which something resembling the methods of the military staff college could be attempted, officers of various departments meeting in study groups to work out hypothetical or actual administrative problems. Participation of representatives of commerce and industry and other organizations in such discussions is suggested, and the sharing of experience between business men and Civil servants is recognized as mutually valuable.

In recommending the fullest use of the centre for all these purposes, the Committee does not appear to be entirely consistent, despite its belief in the value of contacts between Civil servants and commerce and industry. Moreover, it must be admitted that the Committee does not seem to be sufficiently alive to the dangers of departmentalism, and however unexceptionable may be its further suggestions for training the recruit by discussions, visits, field-work and the like, some legitimate doubt may well be entertained of their effectiveness in dealing with an evil which is not confined to the Civil Service. Something of the same timidity characterizes the discussion of the training of those intended for positions of high administrative responsibility also.

Here the Committee accepts the general view that in the early thirties a complete change of environment or an opportunity to stand back from one's job and to shake oneself free from the daily routine is most desirable to gain a broader vision and some fresh experience. Without questioning the value of transfer within the Service from one department to another, or from headquarters to out-station, or vice versa, for refresher purposes or for widening experience, it rightly insists on the need for opportunity to get away for a time into a different atmosphere altogether, by a period of secondment elsewhere, for example, to outside business or a local authority. The former is regarded as of little value unless for a period of anything up to two years, so that the Civil servant could do a real job of work and be entrusted with real

responsibility. This method is therefore considered one for tentative experiment rather than definite recommendation. Seconding to, or interchange on a two-way basis with, a local authority is, however, a more promising and less difficult way in which the Civil servant should have opportunities for appreciating more readily the impact of action at the centre upon local government and upon the general public. The Committee recommends accordingly that departments such as the Ministry of Health and Board of Education should consider and report on such possibilities. Beyond this, the Committee suggests that selected Civil servants, say in the early thirties, should be granted a period of sabbatical leave to pursue an approved course or to undertake research, either in Great Britain or abroad. Such leave should be with pay and should count as service for purposes of pension.

The Committee is clearly in sympathy with the proposal of the recent British Association Committee on Post-War Education, but contemplates something beyond the social studies suggested by that report. Again, it takes up a suggestion emphasized in a Planning broadsheet, "A Civil General Staff", in commenting on the ignorance of Civil servants of the relevant experience of other countries, and strongly commends the idea of giving selected officials an opportunity of travelling abroad to study aspects of government or public administration likely to be of value. Study of the way in which problems of government are tackled abroad would be worth while in itself as a safeguard against insularity, as well as providing a stimulant which would be of great benefit to the Service.

The Committee does not overlook the current criticism that the Civil Service is not sufficiently alive to the possible effect of its actions upon business undertakings; and that its members, in those departments which come into daily contact with commerce and industry, should be equipped with a fuller understanding of their problems. This contact, it suggests, should be secured by visits and periods of observation, varying in duration from a week to a maximum of two or three months. By such arrangements it is believed that selected Civil servants might acquire a better insight into the methods and problems of the industrial and commercial world, while at the same time business men might gain a better understanding of the point of view of the Civil servant.

There can be no doubt that a number of these suggestions need to be explored seriously and thoroughly and with some urgency, whether or not the Committee is unduly optimistic as to the effect, particularly of this last suggestion. On the other hand, the Committee is assuredly correct in pointing out that the need for Civil servants to acquire the right attitude of consideration and sympathy towards the public should not lead us to forget that this attitude should be mutual. A spirit of service cannot be expected to flourish among public servants if they feel with reason that their efforts are being disparaged and their difficulties overlooked by those whom they are endeavouring to serve. A more generous appreciation by the public of the work of the Civil Service would go far to ensure that such appreciation was increasingly deserved. It is somewhat surprising that the Report appears to overlook the influence which the considerable number of temporary Civil servants recruited for war purposes—estimated in a debate last year at some 300,000—might well exert in this respect; but the point is one which should not escape the public relations officers of the Service.

The Report must now be subjected to constructive and informed criticism, to ensure that full advantage is taken of any fresh experience acquired as a result of the experiments which the Committee suggests. Judgment may well be reserved on a number of points: some of the present defects may be more deeply embedded in the administrative system than the Report admits. Here, however, is positive and constructive criticism comparable with that which characterized the report of the Select Committee on National Expenditure. Defects are laid bare and weaknesses admitted, and it is unthinkable that the situation will remain as it is. Neither the Government nor the Civil Service can allow the charge of neglect of systematic post-entry staff training in peace-time to be levelled again. Whether or not the measures at present advocated are entirely adequate to attain the objectives so admirably stated, they should at least promote the ever-present consciousness of the importance of clarity of thought, directness of action, simplicity of expression, speed, initiative, considerateness and other virtues, in which Civil servants are often said to be deficient—and which are not always conspicuous in their detractors. The Report clearly believes that training and good staff management will do much to make these the keynotes of daily practice in all ranks from the highest downwards, and the confidence it shows thereby in the essential qualities of the present Civil Service in Great Britain is in keeping with the whole spirit of the searching debate in the House of Commons which initiated the inquiry.

# FARMING IN WORCESTERSHIRE, PAST AND PRESENT

**A History of Worcestershire Agriculture and Rural Evolution**

By R. C. Gaut. Pp. xvi+490. (Worcester: Littlebury and Co., Ltd., 1939.) n.p.

WORCESTERSHIRE is one of the smaller counties of England and is neither a tourist nor a holiday resort; but connoisseurs know it as one of our most interesting regions. Through it pass three peaceful and attractive rivers, the Severn, the Avon and the Teme; its scenery is varied by Bredon Hill, the Malverns, the Clent and Lickey Hills and by the Forest of Wyre. Some of the most intensive culture in England is to be found in the Vale of Evesham. The county is rich in archæological interest, for the monastic movement played an important part there, and parts of the great Abbeys of Evesham and Pershore still survive in a setting enriched by interesting churches, attractive country houses and quiet, pleasing villages.

Mr. Gaut has had a long and honourable connexion with the county as its chief agricultural adviser, and

he has had the energy and enterprise to record his unique knowledge of its agriculture past and present.

Records of varying degrees of completeness go back to very early times, and Mr. Gaut begins with the Celtic settlements, of which, however, very little can be said. His method here is to fit the local information into a more general framework, thus giving the book a wider interest than would be attached to a purely local history. From Norman times onwards much more material is available; Domesday Book, the Inquisitions, church records and other sources are all utilized. In the thirteenth and fourteenth centuries sheep seem to have been the mainstay of the agriculture: a wether in good condition weighed about 40 lb. and yielded about 1–1½ lb. of wool, worth about 3*d*. per lb. Several diseases were troublesome; 'rot' was prevalent in wet seasons and there was much scab, for which iron sulphate, verdigris and mercurial ointments were used until the fourteenth century, when tar became the universal medicament for skin diseases. Sheep seem to have been worth about the same as wild rabbits. The carcase weight of the cattle was about 400 lb.; oxen were worth about 11*s*. each. Early horticultural records are scanty; but the county appears always to have produced good vegetables and fruit, including vines. Specialization had not yet begun, however, and Leland, who visited the Vale of Evesham in the years about 1540, was impressed not by its fruit and vegetables but by the quality of the corn grown there. Even then, however, the orchards of the county were notable, for they are praised in a Latin distich of Henry VII's time (1485–1509), which we should like to have seen quoted.

From the seventeenth century onwards the references to fruit and vegetables become more numerous: they may have gained in importance as the forests were cleared to provide wood for the making of charcoal for the smelting of iron. There are early eighteenth-century complaints that hops and potatoes were "destructive to land because they breed no manure: they take from it, but give nothing back to earth". Leases imposed a penalty of £5 per acre for breaking up grassland to grow hops or corn without permission. There is a curiously modern ring about the further complaint that hops are bad for the farm because they receive all the manure, nothing being left for other crops.

By the second half of the eighteenth century the special character of Worcestershire agriculture was already established. In 1782 the Vale of Evesham was described as "the Eden of England in respect to gardening". In some years, the account continues, one hundred thousand bushels of cucumbers were sent to the different neighbouring counties; asparagus went to Bath and Bristol; early potatoes, kidney beans, lettuce, broccoli, cauliflower, endive and other vegetables were produced in quantity.

Marked progress in horticulture set in after the formation of the Royal Horticultural Society in 1804; this stimulated the formation of local societies, which by their shows and premiums greatly encouraged the introduction of better methods and the selection of improved varieties of crops. Accounts are given of the activities of some of these early societies and of the gardeners and nurserymen of the county to whom so much of its subsequent progress is due.

But all Worcestershire is not market gardening, and the heavy-land farmers passed through a very difficult period in the latter part of the nineteenth century: by 1877 thousands of acres were tenantless. Wheat had been the chief crop, and to maintain soil fertility the farms had been well stocked with sheep and cattle. The ancient practice of burning the stubble still survived and was considered highly beneficial. Fortunately not all farmers suffered so badly: Benjamin Bomford, described by Mr. Gaut as the greatest arable farmer Worcestershire has ever produced, learned to use big farm machinery and added farm to farm until at his death in 1880 he was farming some six thousand acres. It is said that on one occasion he brought together and set to work for his guests £9,000 worth of steam tackle which in a few hours ploughed an area equal to that of a good-sized farm. Happily, his descendants have continued to develop farm mechanization and to maintain the family tradition of efficiency and hospitality: it is not long since the writer attended with special pleasure a demonstration of modern implements and methods on one of their farms.

The Worcestershire County Council was set up in 1888 and soon began to arrange for agricultural education. In 1891 it made grants for the establishment of a County Dairy School and for the work of the Chamber of Agriculture and the Union of Workmen's Clubs; but the procedure was soon changed and the County Council itself undertook to provide instruction.

The County narrowly missed having one of the early schools of agriculture for farmers' sons. In 1898, Mr. John Corbett of Impney Hall offered to devote £50,000 for foundation and maintenance; but various legal difficulties arose and a special Act of Parliament was being drafted when the outbreak of the South African War put an end to the negotiations. Meanwhile, other provision was being arranged by the Board of Education. Later on, in 1925, the Avoncroft Residential College for Rural Workers was opened at Offenham and ten years later transferred to Stoke Heath. An experimental garden was established at Droitwich, but will now be transferred to Norton Hall, Worcester.

As in other counties, the population of the purely agricultural parishes has declined: in the cases quoted the fall from the peak in 1871 to what one hopes will prove to have been the minimum in 1931 was about 30 per cent; on the other hand the populations of the market-gardening parishes have gone up: some have more than doubled.

The book is full of interest and can be strongly recommended to all who are concerned with country life, agriculture or horticulture. In a future edition it would be well to insert some maps: these would heighten the value of the book and would considerably elucidate the text.

In other counties also there are men who have long served their farmers and growers and who have very full knowledge of the county agriculture. It is greatly to be hoped that they will follow Mr. Gaut's excellent example and record the information while the men who passed through the revolutionary changes of the past forty years still survive to give those details without which agricultural statistics are very lifeless. The success of the reconstruction after the War will depend on the amount of sound knowledge that can be put into it, and if each county could have as full and illuminating a record as this which Mr. Gaut has prepared, we could indeed feel that the basal facts were available to all charged with the duty of carrying out what is bound to be a difficult task.

E. J. RUSSELL.

# LIMITS OF EXTRA-SENSORY PERCEPTION

## Paranormal Cognition

Its Place in Human Psychology. By Dr. Laurence J. Bendit. Pp. 79. (London: Faber and Faber, Ltd., 1944.) 5s. net.

THIS short essay contains the substance of a thesis recently submitted to the Department of Medicine of the University of Cambridge, and approved for the degree of doctor of medicine. Although it contains little from the medical point of view and would seem more suitable as a thesis submitted to some psychological faculty, the book is of interest as it directs attention to a question which is bound to excite greater attention as time goes on.

For the purpose of his work, Dr. Bendit takes it for granted that what he calls "psychic" modes of perception exist apart altogether from the ordinary channels of sense. Indeed, he maintains that "science to-day accepts as fact that man has channels for obtaining knowledge of the world about him which are not those of the ordinary senses". Although he does not say what he means by "science" in this connexion, it is clear that the statement does not apply to scientific men taken as a body, although the opinions of the chemist on questions of parapsychology are no more valuable than those of the parapsychologist on chemistry unless both parties have studied each other's interests.

In the present volume Dr. Bendit assumes that what he calls paranormal cognition is a fact, and under this name he includes a number of forms of perception which do not fall within the range of abnormal hyperacuity of the senses but beyond them into a region where normal perception, however acute, no longer operates. Thus the 'paranormal cognition' of Dr. Bendit includes what the American school calls 'extra-sensory perception', although he seems to extend the scope somewhat to include other phenomena the precise nature of which is still a subject of controversy.

In the course of his discussion the author mentions the possible emergence of such material in the statements and dreams of patients undergoing psychological treatment; and he appears to think that the reports of psycho-analysts who state that they have found such instances among their patients constitute "an important class of literature" in this connexion. This brings us to the most important part of Dr. Bendit's thesis, in which the author seems to have fallen (or appears about to fall) into what might be grave sources of error of a type which have vitiated so much serious work in the past. Having become convinced that paranormal cognition is a fact, he goes on to assume that it can be suspected in cases contributed by persons, some of whom he names, whose work can only be regarded with much scepticism as to its reliability. Indeed, Dr. Bendit is so anxious to suggest that such cognition is widely distributed that he uses the work of E. N. Marais on termites as an example, although few entomologists would regard the theory of this author as proved, and indeed it has been characterized by one critic as "a poetical invention which gets us nowhere". It is the growth of this tendency to see something 'psychic' in phenomena hitherto not fully described or adequately studied that so many psychical researchers feared might be the result of an acceptance of some form of paranormal cognition on the basis of properly controlled and statistically analysed experimental data. One of Dr. Bendit's own collaborators in his thesis, to whose "specialized knowledge and experience of psychic matters" he owes a good deal, has published some of the results of using her alleged power of paranormal cognition, and it appears that she accepts many of the so-called physical phenomena of mediumship, including such almost wholly discredited manifestations as apports and slate-writing, and even claiming through her paranormal 'vision' to see the so-called ectoplastic rods used in levitating tables! How far Dr. Bendit is right in believing that these remarkable results are justified is for himself to judge. Others may be tempted to accept paranormal cognition just as far as the results of scientific experiment may compel them to do so, leaving the vast inchoate mass of borderland psychological phenomena to be included or rejected as our knowledge increases and as the range of our experiments becomes extended.

E. J. DINGWALL.

# A RUSSIAN TRIBUTE TO NEWTON

## Isaac Newton, 1643–1943

(In Russian.) Pp. 82+4 plates. (Kazan: Kazan Aviation Institute, 1943.) 10 roubles.

THIS booklet contains four addresses read at the celebration of Newton's tercentenary on April 9, 1943, in the Institute of Aviation in Kazan. The plain fact of such a celebration when a vital part of the U.S.S.R. was still under the German yoke is noteworthy, especially when it is realized that the man thus honoured was, after all, for Russians, a foreigner. In the general introduction and also in two of the addresses the same comment recurs—the U.S.S.R. celebrates Newton's memory amidst all her war-time occupations and worries, since she is fighting for "freedom of scientific, artistic, and philosophical creation".

In the first address, Prof. M. M. Kusakov reviews Newton's life and work, including his theological publications. Kusakov considers Newton to be the founder of the prevalent philosophy of the men of science of eighteenth and nineteenth centuries, which "represents a combination of primitive mechanical materialism with deism".

The fourth paper, by L. F. Rakusheva, deals specially with Newton's philosophy. Apparently, Newton did not bother to formulate his philosophy, if he had any; and the clarity and precision of his physical and mathematical passages contrast with his timid and contradictory pronouncements on philosophical problems. But Newton's scientific discoveries had a decisive effect on later philosophers. Quotations from Marx, Engels and Lenin show the relation between Newton's point of view and that of the dialectical materialism.

P. M. Dulski spoke on Newton's iconography. Unfortunately, the material expected from the Royal Society did not arrive, and the lecturer had to use only well-known published sources.

B. Stolbov gives an interesting account of Newton's optical work. He states that, contrary to the usual belief, Newton was just as much inclined to the wave theory as to the corpuscular theory of light.

J. J. BIKERMAN.

## Illustrated Technical Dictionary

Containing Standard Technical Definitions of Current Terms in the Applied Sciences, Graphic and Industrial Arts, and Mechanical Trades; including Air Navigation, Meteorology, Shipbuilding, Synthetics and Plastics; with Illustrations, Technical Data and Interconversion Tables. Edited by Maxim Newmark. Pp. xii+352. (New York: Philosophical Library, Inc., 1944.) 5 dollars.

TECHNICAL dictionaries are multiplying rapidly to meet the growing needs of a progressive civilization, and the Philosophical Library, New York, is placing itself in the vanguard of publishers who respond to this demand. Its new illustrated technical dictionary will be welcomed by scientific and technical workers of almost every kind; the book should find a home in most general libraries. The explanatory sub-title gives a good idea of its scope, with the emphasis on the mechanical arts, and the illustrations, which have been supplied mainly by engineering firms of standing, will be found very useful. The multiplicity of subjects and the necessarily limited space will doubtless invite some adverse criticism concerning lack of balance; but what may be important to the engineer or 'wireless' expert may be of little interest to the chemist, and vice versa. A primary consideration is that first things should be placed first, and in this respect there is little to cavil at in the present work; only a few slips and omissions have been noticed. The definition given of permeability refers only to gaseous diffusion: electric and magnetic permeability are not mentioned. The Baumé hydrometer is defined as a *scale* for measuring the density of a liquid. The chief use of ammonium sulphate, namely, as a fertilizer, is not given, nor is the use of urea in the manufacture of plastics. The uses of so many chemical products for so many purposes suggest that there is scope for a separate publication on this subject. It would be compendious and need constant revision, but it would be a boon to many manufacturers and industrialists; and it would form a useful companion volume to the present work of reference. E. H. T.

## Joint Progress Report on Reservoir Efficiency and Well Spacing

By the Committees on Reservoir Development and Operation of the Standard Oil Company (New Jersey) Affiliated Companies and of the Humble Oil and Refining Company. Pp. xix+77. (New York: Standard Oil Development Co.; London: Anglo-American Oil Co., Ltd., 1944.)

THIS report embodies the findings of two committees appointed respectively by the Standard Oil Co. (New Jersey) Affiliated Companies and the Humble Oil and Refining Co. to collate and interpret data on the effects of field operating practices and well spacing on the efficiency of oil recovery from natural underground resources. Each of the committees carried out pool studies of actual fields to obtain information on reservoir behaviour and oil recovery under various well-spacing and operating practices, in addition to a review of all available theory and research data.

It is concluded that the degree to which basic oil recovery mechanisms (dissolved gas drive, gas cap drive and water drive) will operate in practice, and possible oil yields obtainable, together with optimum economic well-spacing for a particular field, are dependent on physical conditions in the reservoir and on the limiting effect of economics or other imposed restrictions. Probably the most important physical factors governing potential recovery are sand permeability and oil viscosity, high permeability and low viscosity being nearly always conducive to high yield. Economic conditions determine the point at which operations must be abandoned for reasons of cost, and equally they govern decisions on optimum well spacing. As a result of their studies the committees advocate that the securing and recording of requisite data should be a major objective in field development and operation. Records required from each individual reservoir include data on structure and sand-thicknesses, complete analyses of sub-surface samples of reservoir fluids, sub-surface pressure survey readings, productivity factors, and gas, oil and water production figures.

## Introductory Magnetism and Electricity

By T. M. Yarwood. Pp. vii+159. (London: Macmillan and Co., Ltd., 1944.) 2*s*. 6*d*.

IN writing this small volume, the author has provided mainly for those preparing to enter one of the technical branches of the Services. It should be very suitable for cadets in the Air Training Corps. The subject-matter admirably covers all that is necessary in pre-service training. In this, it fulfils one of the two objects stated in the preface. It might not be, however, so successful in achieving the other, which is to stimulate further reading in the subject. It is too condensed and 'heavy-going' to be inspiring to the beginner.

It is surprising that alternating current is not dealt with at greater length. One would have expected to find a whole chapter on this topic.

The book is well arranged and well printed, with many diagrams. Its chief defect is the limp cloth binding. It is to be regretted that war-time economy does not permit a more attractive and permanent binding.

At its published price the book should have a good circulation and is, without doubt, an excellent, though brief, text, superior to many others at much higher prices.

## Manual of Laboratory Glass-Blowing

By Prof. R. H. Wright. Pp. ix+90+11 plates. (Brooklyn, N.Y.: Chemical Publishing Co., Inc., 1943.) 2.50 dollars.

IN this manual the author describes a number of processes which are constantly needed for the construction of laboratory glass apparatus. After discussing the composition and the characteristics of various glasses, a description is given of tools and their usage in the construction of both simple and advanced types of glass apparatus.

In dealing with such a subject no written directions can take the place of personal instruction or individual skill, so that the value of such a manual is enhanced if the diagrams show salient features of the process in progress. The author has attempted to do this by means of original photographs.

The book contains much useful information, and will be of service to the laboratory worker. Its usefulness would have been further increased, at least for the beginner, if more details had been given as to the most suitable gas or oxy-gas flame to use for various types of work. A. J. A.

# TRANSFORMATION OF CELLS AND VIRUSES

By Dr. ALEXANDER HADDOW

Chester Beatty Research Institute, Royal Cancer Hospital (Free), London, S.W.3

RECENT papers by Rhoades[1] and by Sonneborn[2], the first describing a new case of genic induction of a transmissible cytoplasmic difference (the earliest example of which is due to Imai[3]), and the second concerning a novel system of relations between the nucleus and cytoplasmic substances in heredity, are of considerable potential significance for the study of differentiation and growth, both normal and abnormal. Nowhere is this greater than in the field of cancer, where the prospect they afford of a clearer understanding of cytoplasmic inheritance must elucidate some at least of the fundamental problems involved. What these problems are, may briefly be considered.

## Genetic Relationship of Normal Cells and Cancer Cells

In the entire biology of cellular variation, the transformation of normal somatic cells to cancer cells may properly be regarded as a special case, although not necessarily a unique one[4]. The alteration involves some loss of differentiation, and a nearly concomitant gain in rate of growth, the extent of which is a characteristic and permanent property of individual tumours. In ordinary conditions the change is not reversible, so that the malignant variant continues to grow, whether in the original host or on grafting to new hosts, indefinitely, without restriction, and hence with every sign of marked competitive advantage as compared with the normal form. The new cell type can be evoked at will by the use of a wide variety of physical and chemical agents (notably by X- and ultra-violet radiation, by radium and other radio-active elements, and by the carcinogenic hydrocarbons and other compounds both related and unrelated), and we now possess a considerable knowledge of their possible modes of action, of the changes they effect in the cell economy, and of the ways in which the metabolic properties of the malignant cells, in certain cases, may differ from those of their normal precursors.

Much less is known of the precise genetic relationship between the two forms. While many observers have been impressed, justifiably, by evidence which suggested the modification or loss of growth-regulating genes as a primary factor[5], these impressions are such as it is impossible to prove by ordinary genetical methods, that is, in the absence of sexual reproduction as a test. As Haldane expressed the position[6], "cancer cells do not reproduce sexually, and it is only by sexual reproduction that the geneticist can distinguish nuclear changes from plasmatic changes or virus infections".

Short of any decision, much other information, albeit of a secondary or collateral kind, or incomplete, has been derived from the study of genetic constitution as determining rates of susceptibility (whether to the spontaneous development of specific types of cancer, or to the action of carcinogenic substances), and secondly, by the production of tumours through hybridization. Thus spontaneous tumours occurring in the $F_1$ hybrids between *Nicotiana glauca* and *N. langsdorfii* have been ascribed to a cytoplasmic disturbance brought about by the introduction of chromosomes of *langsdorfii* into the cytoplasm of *glauca*[7]; and cross-breeding of *Mus musculus* and *M. bactrianus*, which differ widely from each other in size, fertility, and rate of growth, leads to a considerably augmented incidence of epithelial and connective tissue tumours in the first generation hybrids[8].

Although the nature of his material does not always allow the application of genetical methods, the student of cancer is nevertheless dependent on contemporary genetics to assist him in deciding which at least are the feasible mechanisms in the origin of tumours. To the present time, questions of detail have been wholly obscure, and it has always seemed likely that their solution must ultimately depend upon advances in cytogenetics as a whole. Furthermore, certain accepted characteristics of tumour cells have appeared, until comparatively recently, inexplicable and perplexing by ordinary tenets. This specially applies to the recognized irregularity of the chromosome equipment in cancer cells: while in given tumours no nuclear abnormality may be discernible, other cases present every appearance of extreme heterogeneity. In contrast with this is the fidelity and specificity with which the structural and physiological features of individual tumours are maintained, often through hundreds of transplanted generations, and apparently indefinitely. The matter has been summarized by Mohr[9]: "This pronounced uniformity of tumour tissue as regards phenotypical characteristics is just the opposite of what we would expect from the exceedingly variable chromosome relations of the tumour cells".

## Cytoplasm and Growth

Considerations of this kind have led some few workers[10] to the belief that malignancy is attributable to a cytoplasmic alteration, and Koller[11] carried out an analysis of aberrant chromosome and spindle mechanism in malignant cells in an endeavour to correlate this with the behaviour of the nucleolus, which appears to hold a key position in the interrelations of nucleus and cytoplasm[12]. These anomalies have also stimulated an interest in evidence from other fields, that the more general and fundamental activities of the cell can take place even in the absence of the chromosome apparatus (if only for a time), and are governed to some extent by elements present in the maternal cytoplasm. For example, evidence has been sought[13,14,15] whether cleavage-rate in echinoderms is a function of the cytoplasm or of the nucleus. In hybridization and other experiments (with Dendraster and Strongylocentrotus) the speed of fission, in every case, was that characteristic of the cytoplasm. Secondly, E. B. Harvey's studies[16] of the growth of enucleated egg fragments (for several echinoderm species and in the annelid Chætopterus) in parthenogenetic merogony, that is, where maternal and paternal chromatin are entirely lacking, appeared to modify, or even to minimize, the role of the chromosomes and genes in early development.

Since in nearly all species the properties of the cytoplasm are controlled by the chromosomes, and because cytoplasmic factors which can be perpetuated in the absence of the appropriate chromosomes have been recognized only in exceptional cases[17] and almost entirely in plants, the problem takes the form whether the capacity of the cytoplasm to determine growth is due to a chromosomal effect persisting after removal of the nucleus, or whether it is innate and independent.

## Cytoplasmic Transmission of Breast Cancer in Mice

Cognate questions arise from the so-called 'extra-chromosomal' transmission of breast cancer in mice. Since mammary cancers were found to arise with special frequencies in certain strains, attention was directed at an early stage to the presumptive importance of genetic constitution, as a factor determining the origin of such growths. The tumour-rate in hybrid strains was studied by Lathrop and Loeb[18] as long ago as 1918, when they wrote: "... the fact ... that several times (but not in all cases), in reciprocal crosses, the hybrids followed the tumour rate of the mother strain, suggests the possibility that as far as the hereditary transmission of mammary cancer in mice is concerned, the mother may be more important than the father. . . ." Much later, the role of the female sex hormone was disclosed, from records of the varying incidence of cancer in virgin, breeding and ovariectomized females, by ovarian transplantation in castrate males, and by artificial administration of œstrogens to both males and females.

Further progress followed the establishment of homozygous strains, when the importance of the maternal factor was clearly established by reciprocal crosses[19]. Bittner then discovered[20] that the cytoplasmic factor is conveyed by the mother's milk, and that when young from mothers of a high-incidence line are suckled by mothers from low-incidence lines, the frequency of breast cancer in the fostered females is very considerably reduced. It is now known that the agent is present in tumour tissue, the lactating mamma, and many of the organs of high-incidence lines, and that it retains its potency in lyophilized, desiccated or glycerolated tissue, and in Seitz filtrates. Although its exact nature is not certain, it is probably a colloid of high molecular weight[21], with properties suggesting virus activity, and may seemingly arise *de novo* apart from contact[22].

According to W. S. Murray[23], the degree of mammary cancer which appears in any generation is dependent partly upon the concentration or amount of the extra-chromosomal factor which the mother transmits, and partly upon the resistance or receptiveness of animals of various genetic constitutions to this stimulus. There still remain considerable differences of opinion regarding the relative importance to be attached to the three components (cytoplasmic, nuclear, and hormonal), whether separately or in interaction. van Gulik and Korteweg[24] apparently believe that the cytoplasmic factor becomes inactive after a number of generations when a chromosomal factor is not present at the same time. But from Bittner's most recent statement[25] hormonal stimulation, inherited susceptibility (which was transmitted by males and females of cancerous stock as a dominant), and the milk agent, are of approximately equal etiological importance in mice of known constitution under normal conditions: "that is, any one of the three factors or influences may be completely determining in its effects".

## Filterable Agents of Avian Tumours

A final problem concerns the induction of malignant change in normal connective tissue cells (more strictly the free histiocytes) in birds, by means of a submicroscopic and particulate agent extractable from the cells of tumours of the avian mesenchyme, of which the virus of the Rous chicken sarcoma I is the best known example. Tumours arising after inoculation of this and similar agents are derived from the prototype cells of the recipient host. They invariably conform in the minutest detail with the growth from which the agent was obtained, and they usually continue in their turn to produce further large amounts of the specific virus. In serological experiments[26] the purified Rous agent is neutralized by the serum of rabbits immunized with normal fowl serum or with normal fowl tissues, and stronger neutralization is obtained with the sera of rabbits immunized with large quantities of the purified agent itself. Further, both anti-fowl and anti-agent sera are deprived of neutralizing activity by absorption with normal chick embryo. The Rous I agent therefore appears to contain (in addition to a specific antigen) a second antigen which is also present in normal fowl tissue—a relationship which is possibly unparalleled in the whole range of animal viruses. The discovery of the Rous agent was made more than thirty years ago, and it represents one of the key observations of cancer research: yet here again it is likely that full comprehension can only be achieved through fundamental advance in other fields, such as is promised by the newer trends referred to, and the implications of which may be examined.

## Cytoplasmic Determinants and their Gene-controlled Mutation

Possibly the earliest relevant observation was made by Imai[3] when he described random and irreversible mutation of a proportion of green plastids (giving green cells) to white plastids (giving white cells) in the recessive 'variegated' homozygote of barley. These plastids showed maternal transmission, and the white plastids proved autonomous and independent of nuclear control or activity, since they did not return to the green condition even under the influence of the 'green' nucleus.

Rhoades's contribution[1] concerns the gene-controlled character *iojap* in maize. Plants homozygous for the recessive gene (*ij*) develop a chlorophyll striping or variegation, interpreted as due to induction, by the gene, of modification in the plastid. Evidence is given, as for Imai's case, that the modification is irreversible, that the variant plastid possesses genetic continuity, and that this is thereafter independent of nuclear control: the mutant plastid continues to give rise to mutant plastids, in cells of whatever nuclear constitution (*ij ij*, *Ij ij*, *Ij Ij*). These relations are suggestive—and Rhoades clearly recognizes their bearing—of a mechanism whereby the expression of growth, the rate of growth, and the closely associated property of degree of differentiation, might be governed by a system of independent entities in the cytoplasm.

A more complex arrangement is revealed in Sonneborn's study of the heritable characters 'killer' and 'sensitive' in diverse races of *Paramecium aurelia*. Fluid in which the killer race has lived, kills individuals of the sensitive races, and when pure races of the two types were crossed, the two exconjugants of each pair were found to produce phenotypically different clones. It was then demonstrated that the $F_1$ killer clones derive their cytoplasm from the killer parent, and that the $F_1$ sensitive clones are those with cytoplasm from the sensitive parent. By means of technically favourable material, the phenomenon was shown to be not cytoplasmic inheritance simply, but the continued production of a cytoplasmic sub-

stance under the influence of the single gene $K$. *Addition of the cytoplasmic determinant to an organism, lacking the character dependent on it, but containing the required gene, results in the continued production of the cytoplasmic substance, in the development of the character determined by the combined presence of gene and cytoplasmic substance, and in the hereditary maintenance of the character in successive generations.*

The potential significance of these relations, both for the cytoplasmic transmission of mammary cancer and the propagation by virus of the Rous sarcoma, is sufficiently striking. They also exemplify the characteristics of cytoplasmic inheritance described by Darlington[27]: "... not only co-adaptation of the types of nuclear gene and plasmagene but also some degree of genotypic control in regard to the conditions of reproduction and equilibrium of the plasmagene".

## Nature of the Cytoplasmic Entities: Plastogenes, Plasmagenes and Viruses

Apart from the visible plastids responsible for cytoplasmic inheritance in plants, the nature of the cytoplasmic entities remains a matter of conjecture. It is therefore reasonable to inquire what light may be thrown on cytoplasmic determiners by recent investigations of the morphological and chemical structure of protoplasm, and especially of the submicroscopic particles (microsomes) of Claude[28]. These range in size from 0·06 to 0·2 $\mu$, and allowing for certain quantitative differences, present many similarities to the mitochondria, and appear to serve as centres for enzyme localization, both, for example, being capable of oxidizing succinic acid and giving a reaction for cytochrome oxidase[29]. Chemically, the microsomes have been found to be complex structures composed of ribose nucleoproteins and phospholipids, associated in definite proportions. By differential centrifugation, Claude isolated the active fraction from chicken tumour extracts in a form resembling fractions obtained from normal chick embryo by the same method; and he further finds that an important and possibly essential constituent of the tumour-producing particles, as of the normal microsomes, may be a nucleic acid of ribose type. The size of the Rous agent has now been determined by electron microscopy (0·07–0·1 $\mu$), as well as in the ultracentrifuge (0·07 $\mu$)[30]. In shape the particles are short ellipsoids, and fairly homogeneous from electrophoretic behaviour.

With the suggestion of an intrinsic origin for the avian tumour viruses may be related the view that many of the plant viruses are autocatalytic proteins of ultimate host-cell origin; and both possibilities should be compared with those different but partly relevant hypotheses which envisage many viruses arising by a process of retrograde evolution, that is, by a progressive loss of enzyme systems and synthetic functions and an increasing degree of dependence upon the cellular host[31,32]. Woods and DuBuy[33] have recently brought evidence that the characteristics of plastid-controlled variegations are intermediate between those of normal plants and virus-diseased plants, and have endeavoured to connect virus proteins phylogenetically over the variegation-inducing agents (abnormal plastids) with proteins of the normal plastids. They also attempted graft transmission of plastid-controlled variegation, which would afford direct proof of the ability of abnormal plastids to infect, and invade, previously normal cells. Although these experiments were mainly negative, such graft invasion has already been established as the cause of variegation in a number of plant species, and there is little reason to doubt that variegation-inducing plastids frequently behave like viruses, just as the plant viruses have properties often shown by plasmagenes in interspecific crosses[27]. In particular, it is likely that the changes evoked by many viruses are due to their competing for substrate with physiological elements of the cell, and thus diverting the normal metabolism. From Darlington's interpretation of Sonneborn's data[41], the 'sensitive' plasmagene in Paramecium, which is determined by the action of a nuclear gene, is suppressed by the competitive reproduction of another plasmagene. So too the variegation-inducing plastids can multiply in previously normal cells, and may restrict the development of normal plastids in those cells. The manner in which the influence of plant viruses can be likened to that of agents already present had already been noted by Stanley[34].

## Induction of Heritable Change in Bacteria and Viruses

Sonneborn compared the system of determination and inheritance in Paramecium with the environmental control of genetic characters in bacteria, especially with the inter-conversion of specific types of Pneumococcus. This phenomenon was first described by Griffith[35], and it depends upon the degradation of a given specific, virulent, 'smooth' type ($S$), possessing the characteristic capsule with its specific polysaccharide antigens, into a non-specific, avirulent, 'rough' variant ($R$), lacking these features but convertible into the same or another specific and differentiated type ($S$) by growth in the presence of heat-killed $S$ cells of the type to which conversion is desired. The transformation was afterwards induced by means of sterile extracts of $S$ cells[36], and represents one of the most striking examples of the artificial induction of heritable change. The agent required for conversion was recognized to be not the specific polysaccharide itself, but some other component of the $S$-type cell, and Avery and his co-workers[37] have now isolated from type III pneumococci a desoxyribonucleic acid fraction which is capable of transforming unencapsulated $R$ variants (derived from type II pneumococci) into fully encapsulated type III cells: the inducing substance appears to be a highly polymerized form of sodium desoxyribonucleate. It is a striking fact that the substance evoking the reaction, and the type-specific capsular substance produced in response to it, are chemically distinct. Once transformation has occurred, the newly acquired characteristics are thereafter transmitted without any further addition of the transforming agent; and from the transformed cells themselves a substance of identical activity can be recovered in amounts far in excess of that originally added, or needed, to induce the change. Assuming the transforming activity to be an inherent property of the nucleic acid, its biological specificity remains to be explained on a chemical basis. Little is known of the effects which slight differences in molecular configuration may exert on the biological action of this class of compound, although the constituent units and general structure of the nucleic acid molecule have been defined: this in itself must represent an entirely new and highly promising field.

A similar principle probably obtains for certain virus transformations. Berry[38], applying the methods discovered by Griffith, succeeded in changing the virus of rabbit fibromatosis (Shope)—in which the

lesions consist of masses of spindle-shaped cells which may recall the structure of malignant connective tissue tumours—into that of infectious myxomatosis (Sanarelli), a highly contagious disease in which tumour-like formations appear in the sub-epidermal tissues, and in which the type cell is not spindle-shaped but stellate or polygonal. In this case, however, the reaction is initiated only with difficulty, and a large excess of the transforming factors is required. A serological connexion between the fibroma and myxoma agents had already been noted, and it would seem that the immunological configuration of the killed myxoma virus particle remains sufficiently intact to provide a template for the formation of active myxoma virus, in the presence of a developing fibroma lesion. This specific mutability is a property of a considerable number of strains of fibroma virus, and the capacity of various myxoma strains to serve as transforming agents also seems to be both general and stable. The factor which induces the alteration of fibroma to myxoma virus is an integral part of the so-called elementary bodies of the latter, and Berry records a number of facts suggesting that the essential substance is the myxoma virus nucleoprotein. The transformation itself has emphasized the close relationships in a single group of viruses, which has been called the fibroma-myxoma 'spectrum', and which is capable of exciting the most widely diverse pathological effects.

## Reversibility of Cellular Changes

By a few workers (for example, Dobzhansky[39]), pneumococcal transformation has been interpreted on genetic lines, the inducing substance (only later recognized as probably a desoxyribonucleate) being likened to a gene, and the capsular antigen which is produced in response to it being regarded as a gene product. The subject has also been of considerable interest to those engaged in the investigation of cancer, and Murphy[40] compared it with the virus propagation of fowl tumours, and coined the term 'transmissible mutagen' to describe the Rous and similar agents. This analogy with a mutation-producing gene is, however, only valid in a general sense, and proves less accurate in points of detail. Thus most observers have been impressed not by any resemblance of $R \rightarrow S$ transformation of pneumococci and the conversion of normal cells into malignant cells, but by the affinities of the latter process with irreversible $S \rightarrow R$ changes in bacteria. Hence, if the Rous virus corresponds with a cytoplasmic determiner, the factor inducing pneumococcal transformation conforms rather with the gene, and it converts a less differentiated cell into a highly type-specific form.

Other points of contrast arise from the differing reversibility of the two changes. Although the susceptible normal cell can easily be rendered malignant on infection with the chicken tumour virus, the tumour cell then continues to breed true, and cannot be re-converted to the normal. For certain instances of bacterial variation the $R$ and $S$ forms are mutually convertible, as we have seen; but in the majority, the $S \rightarrow R$ change is induced with greater facility than the reverse, and in many cases the $R$ type is highly stable, or even permanently so. Sonneborn provides some insight into such relationships from a consideration of the relative mutation-rates, killer $\rightarrow$ sensitive, and sensitive $\rightarrow$ killer, in Paramecium. Mutations from killer to sensitive are expected more frequently than in the reverse direction, since they will occur either if the cytoplasmic factor is lost, or if the gene mutates to a form that cannot control production of the cytoplasmic factor. Contrariwise, mutation from sensitive to killer, in those cases in which the sensitive gene is present, requires both mutation of the gene and *de novo* origination of the cytoplasmic factor. Therefore, mutation in the former direction involves either of two events, while mutation in the latter direction necessitates two events in a given order.

## Implications for Growth and Infection

For the larger questions of genetics and heredity, Darlington[41] has shown the significance, and the stages in its discovery, of a positive influence of the cytoplasm which is based upon unattached determinants, vested in a molecular system depending for its permanence upon a chemical rather than a morphological equilibrium, and which shows a limited capacity for independence of the mechanically stable nucleus. As he makes clear, knowledge of the plastid and cytoplasmic systems was necessarily delayed, and is only now unfolding, since it could only be interpreted in terms of a prior understanding of the nuclear system. The new conceptions are equally certain to produce their impact upon almost every other department of thought in biology, not least in the special problems of the nature of viruses, and of growth and differentiation—problems which have indeed awaited just such an advance, for their proper development.

So far as infection is concerned, it may be recalled that the progress of bacteriology itself involved a not inconsiderable readjustment of ideas. But its spectacular rise as an applied science induced in turn a prevalent unwillingness to regard any agents with biological activity of the nature of infection (and particularly the filterable viruses) as other than entirely specific and independent living organisms. In course of time there gradually accumulated a body of facts, concerned, it is true, with only a few classes of these filterable entities, such as the plant viruses and the avian tumour agents, which nevertheless appeared inconsistent with this orthodox view. Little difference of opinion has ever centred on the validity of the facts themselves: the antithesis is one of theory, and not of observation. The comprehension of anomalous cases was therefore hindered by a too limited interpretation. It is in this sense that the newer development has significance, in facilitating understanding, and on a basis sufficiently wide to include data hitherto appearing incomprehensible, or even irreconcilable. Apart from any question of identity of nature, parallels had already been drawn between the *kinetics* of gene action and virus production[42], and between the X-ray or ultra-violet inactivation curves of both viruses and genes[43]. But in certain cases similarity of behaviour becomes identity, and, for the Rous agent at least, no real distinction can be drawn between its typical activity and that of a mutant plastogene. Especially, this suggestion would account for the strict cytotropic specificity of fowl sarcoma agents, by which each transmits to the new host the characters of that particular tumour alone from which it was obtained.

## Virus Etiology of Cancer in General

This broadened interpretation, valuable as it must prove to be, still affords no rationale of the curious distribution of non-cellular agents in the induction

and transmission of cancer. An agent of the Rous type may not be detected invariably, even in the Rous I tumour, its presence and absence being to some extent correlated with more rapid and less rapid growth of the cells, respectively. Other spontaneous connective tissue tumours of the fowl may completely fail to exhibit such an agent. Again, a comparable agent has not been found in any epithelial tumour, but only in those from avian mesoblast and the type cells of chicken leukæmia[44]. Finally, no such agent is present in malignant mammalian tumours, with the possible exception of leukæmia in mice. Attempts have been made to trace the source of this contrast between avian and mammalian tumours to some inherent cellular difference in the two classes. So far, the only distinction observed is a marked size-variation in avian chromosomes, the smallest particles in the metaphase plates being on the limit of resolution: this range was regarded by White[45] as characteristic of birds in general and quite unparalleled elsewhere.

Indications of infection in the natural history of cancer have rightly attracted considerable notice; but the great mass of fact shows them to be exceptional, and gives little hint of any such process as an indispensable feature of the induction of tumours. In particular, the zoological distribution of the disease —and the occurrence of somewhat analogous tumours in plants—is so wide as to lead us to suspect that the neoplastic change, by which the somatic cell, as it were, re-asserts its individuality, has in its nature something fundamental in biology, and is one to which almost every cell is liable in appropriate circumstances, quite apart from any process of infection in the bacteriological meaning, by independent and unrelated parasitic organisms. The entire evidence which might show that the avian tumour agents are independent parasites relies mainly on their unlimited capacity for multiplication in the presence of susceptible living cells either *in vivo* or *in vitro*, on the fact that cell-free filtrates of certain of the fowl tumours have been found to induce similar tumours in other avian species[46], and on analogy with proliferative although non-malignant lesions, in man and animals, caused by acknowledged viruses in the older sense[47] (for example, the pox diseases epithelioma contagiosum and molluscum contagiosum, the filterable warts of man, dogs and cattle, and infectious papillomatosis of rabbits). The last comparisons are admittedly compelling, but the other criteria have proved less easy to maintain. The first (capacity for multiplication) can clearly no longer be accepted as necessarily attesting the living or extrinsic nature of the material undergoing increase.

Significance has also been attached to the transmission of the Fujinami fowl myxosarcoma to ducks and of the Rous I sarcoma and a fowl endothelioma by filtrate to pheasants, but it is pertinent[48] that transmission in both of these cases is still within the limits of blood relationship as judged by the precipitin reaction: moreover, propagation to the pheasant is within the limits not only of blood relationship but also of bastardization. (Apart from modern examples, it is of interest that Darwin made reference to *phasianus* × *gallus* hybrids in Chapter 9 of the "Origin of Species".) The successful transmission of a fowl tumour to pheasant or duck does not therefore make it less likely that the filterable agent is a cell-derivative on one hand, or more likely that it is an independent parasitic virus on the other.

The discovery of the plasmagene would have held a special interest for Boycott, who always found it difficult to escape the conclusion that the Rous agent arises intrinsically and *de novo*, and who said on a memorable occasion, "if one postulates a normal virus occurring in normal cells, one had better call it something other than a virus"[49].

## Cytoplasm and Differentiation

Both Rhoades and Sonneborn are aware of the implication of their findings for differentiation, in explanation of the fact that while all the cells of an organism presumably have the same genetic constitution in the nucleus, they nevertheless exhibit wide morphological and physiological differences, which are not entirely due to differences in tissue environment: and the view is put forward[1] that cellular differentiation is determined by hypothetical particles in the cytoplasm. The production of different characters in cells with the same nuclear genes would thus be brought about by differential segregation of these cytoplasmic determiners at cell division[2] in a manner similar to that which governs the segregation of plastids. As has been emphasized, the question of differentiation is paramount in the study of cancer. The cells of a given tumour usually show some degree of structural and functional affinity to their normal parent cells: so a cancer of the breast may possess a glandular structure obviously related to the architecture of the normal organ, the cells of a cancer of the liver may retain a considerable degree of resemblance to normal liver cells, and tumours of secretory organs may continue to elaborate the characteristic product, whether hormone or enzyme, of their normal prototype. In general, however, the change from a normal to a malignant cell connotes some loss of special functions, and the tumours of a given lineage can be placed in a continuous series ranging from a near-perfect reproduction of the histology of the parent tissue to a condition in which no specific differentiation can be recognized whatever[50]. The extent of such departure is relatively stable for any given tumour, and the greater it is, the nearer (in many cases but by no means invariably) does the new cell tend to approach an embryonic type and the greater is its rate of growth.

These old and new facts, taken together, suggest a means whereby light may be shed on the central problem of the mode of action of carcinogenic agents other than virus-like influences; that is, the chemical carcinogens obtained by synthesis or from sources outside the body. In our approach to this problem one salient fact overshadows all others: that the growth of the tumour is not in any sense dependent upon the continued presence of the agent which provoked it. In other words, the chemical carcinogen produces a change in the habit of growth of the cell, but as the change is quite permanent, it persists indefinitely after the initial cause has disappeared or has been removed. It is patent that the carcinogen does not provide the real stimulus to growth, since growth proceeds without it. Hence the mechanism which permits unlimited growth must clearly reside in the cell itself. That it may reside partly at least in the cytoplasm, and conceivably in relation to the considerable quantities of ribose nucleic acids which the studies of Brachet, Caspersson and others have shown to be present there when rapid synthesis is taking place, is obviously a possibility for future investigation, both by cytological methods and by experiment.

The new discoveries have, therefore, the widest implications, and for specialized matters no less than for those of a more general nature. In many cases the relationships seem more than mere analogies, and strongly suggest an underlying unity of principle in the growth and differentiation of organisms of the most highly diverse kinds. They also testify to the particular value, notwithstanding its recognized limitations, of the study of variation in unicellular organisms, and sustain the belief, long held by Dobell and others, and now more widely shared, that more than one of the current conceptions in biology must undergo profound modification as a result.

# RECENT DEVELOPMENTS IN POLAROGRAPHIC ANALYSIS

By Dr. JAMES E. PAGE

Glaxo Laboratories, Ltd., Greenford, Middlesex

ALTHOUGH almost twenty years have passed since the polarograph was devised by Prof. J. Heyrovský and his colleagues at the Charles University in Prague, it has only been during the last two years that use of the instrument has been widely accepted by industrial laboratories in Great Britain. Nevertheless, it is now generally agreed that the instrument is of unquestionable value, and the polarograph is taking its place in the equipment of the modern laboratory along with the spectrometer and photo-electric absorptiometer.

The fundamental principles of polarographic analysis were worked out in Prof. Heyrovský's laboratory and have since been confirmed in the United States. These principles are fully described in an excellent monograph by Kolthoff and Lingane[1] which surveys the literature of polarography up to the end of 1940. Since that date, many new applications have been developed, especially in the biological and organic fields, and it is these that I propose to survey.

Polarographic analysis depends essentially on the fact that when a gradually increasing potential is applied to an electrolyte solution in a special cell consisting of a dropping mercury electrode and a second non-polarizable electrode, it is possible to determine from the resulting current-voltage curve both the nature and the concentration of the reducible or oxidizable substance or substances present. It is these current-voltage curves that are recorded by the polarograph.

A typical polarogram obtained with an air-free solution of $0 \cdot 001\,M$ cadmium chloride in $0 \cdot 1\,N$ potassium chloride is shown in Fig. 1. Under standard conditions, the limiting or diffusion current (that is, the height of the step) is proportional to the concentration of the electroreducible substance. This serves as the basis of quantitative polarography. The half-wave potential, which, as its name implies, is the value of the potential of the dropping mercury electrode, standardized against an external reference electrode (usually the saturated calomel electrode), at that point on the current-voltage curve when the current is one-half its limiting value, is a special property of the particular electroreducible substance present and is independent of the concentration of

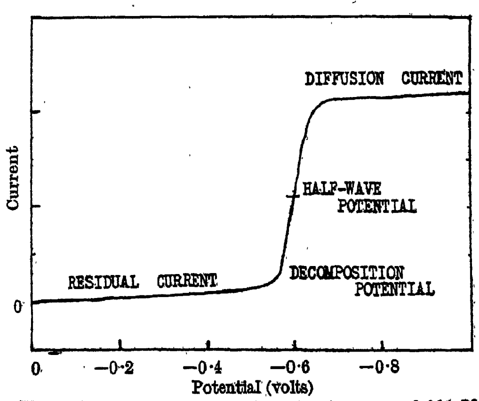

Fig. 1. CURRENT-VOLTAGE CURVE FOR SOLUTION OF $0 \cdot 001\,M$ CADMIUM CHLORIDE IN $0 \cdot 1\,N$ POTASSIUM CHLORIDE.

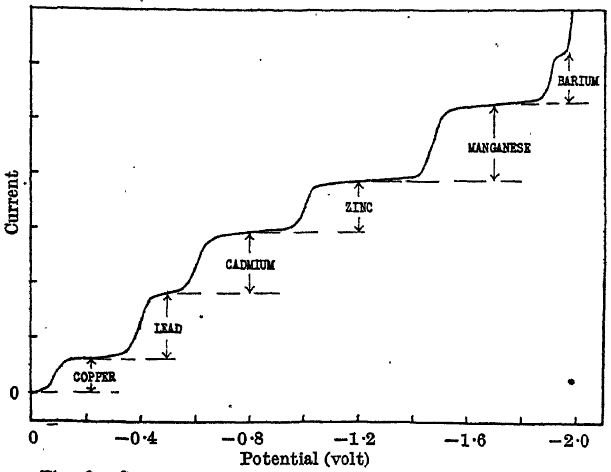

Fig. 2. CURRENT-VOLTAGE CURVE FOR SOLUTION CONTAINING COPPER, LEAD, CADMIUM, ZINC, MANGANESE AND BARIUM IN 0·1 $N$ CALCIUM CHLORIDE.

the substance and of the characteristics of the electrode used. Qualitative polarography is based on this conception.

Theoretically, every substance can be analysed polarographically if it is electro-reducible or -oxidizable within the potential range of the electrode. The maximum range of the dropping mercury electrode is from + 0·6 to − 2·6 V. *v.* the saturated calomel electrode; but for most solutions it is much smaller. If there are several electro-active substances present in the solution, they can all be estimated, provided that their half-wave potentials are at least 0·2 V. apart. Fig. 2 shows a polarogram for a solution containing traces of copper, lead, cadmium, zinc, manganese and barium in 0·1 $N$ calcium chloride. A further separation of steps can sometimes be achieved by altering the $p$H of the solution or by changing the reactants into complexes, from which they are deposited at potentials far enough apart for each step to be measured separately.

The diffusion current is governed by Ilkovič's equation,

$$i_d = knD^{1/2}\, Cm^{2/3}\, t^{1/6},$$

in which $i_d$ is the diffusion current in microamperes, $n$ is the number of faradays of electricity required per molar unit of the electrode reaction, $D$ is the diffusion coefficient of the reducible or oxidizable substance in sq. cm. per second, $C$ is its concentration in millimoles per litre, $m$ is the weight of mercury in mgm. flowing out of the capillary per second, and $t$ is the drop time in seconds.

It has been deduced from theoretical considerations that the constant $k$ should be equal to 605 at temperatures between 15° and 40° C. The approximate correctness of this value has been verified experimentally in the few cases where sufficiently accurate values of diffusion coefficients are available to permit a comparison. In most instances, however, this theoretical constant cannot be used to calculate diffusion current constants with any degree of accuracy, since diffusion coefficient data for the conditions existing in polarographic measurements are not to be found in the literature. These constants must therefore be determined experimentally.

The other factors to be considered in quantitative polarography have been discussed by Kolthoff[2], who has also directed attention to an anomalous 'water wave', which occurs in solutions containing a relatively high concentration of a supporting electrolyte. This step usually starts at about − 0·9 V. and reaches a maximum at − 1·3 V.; but fortunately it can readily be eliminated by adding a trace of gelatin to the solution.

Several investigators have tried to develop schemes of polarographic analysis that would permit the systematic qualitative and quantitative analysis of any mixture of the common metallic elements, but before such a scheme can be developed it is necessary to obtain detailed information about the behaviour of each of the elements under different conditions. Recently, Lingane[3] has published such data for arsenic, antimony, bismuth, tin, lead, cadmium, zinc and copper in various supporting electrolytes, and has pointed out that if the diffusion current constant of a metal is known, there is no need to calibrate each dropping mercury electrode with known concentrations of the metal, provided that the characteristics of the particular electrode are also known.

The polarographic method is widely used in metallurgical analysis for determining trace metals in alloys; but it may equally be applied to the inorganic constituents of a host of other materials ranging from tap-water to various biological products. Since many organic substances are themselves reducible at the dropping-mercury electrode, it is frequently necessary to prepare the biological samples for analysis by special pre-treatments. Such methods have been described for the determination of lead[4], arsenic[5], and vanadium[6].

A special application[7] of the technique has been used for the measurement of ter- and quinque-valent antimony in blood and urine when studying the metabolism of the therapeutic antimony compounds employed in the treatment of bilharziasis and kala-azar. Using ordinary chemical methods, it is difficult to distinguish between ter- and quinque-valent antimony in biological material. However, ter- but not quinque-valent antimony in normal hydrochloric acid solution forms a good polarographic step with a half-wave potential *v.* the saturated calomel electrode at − 0·15 V. (cf. Fig. 3) and consequently can readily be determined in the presence of the quinque-valent form. The latter can be determined after reduction with sodium sulphite. The procedure proved to be surprisingly rapid as well as accurate, so that it was possible to make a large number of measurements, which would have been impracticable by earlier methods. Samples of blood needed relatively little pre-treatment, and urine could be examined directly. Since the half-wave potential for ter-valent antimony is relatively low at − 0·15 V. *v.* the saturated calomel electrode, its characteristic step appears before those due to the other reducible substances in urine. The steps formed by the latter substances would completely mask those produced by small quantities of a substance less readily reducible than ter-valent antimony. A similar procedure may be adopted for the determination of bismuth.

Oxygen dissolved in electrolyte solutions is reduced at the dropping-mercury electrode and yields two distinct steps, the first step being due to the reduction of oxygen to hydrogen peroxide and the second to the reduction of hydrogen peroxide, either to water or hydroxyl ion. The second step coincides with that obtained for the electrolysis of an air-free solution of hydrogen peroxide. These oxygen steps have been extensively used for measuring the oxygen content of a wide range of materials, including body fluids[8],

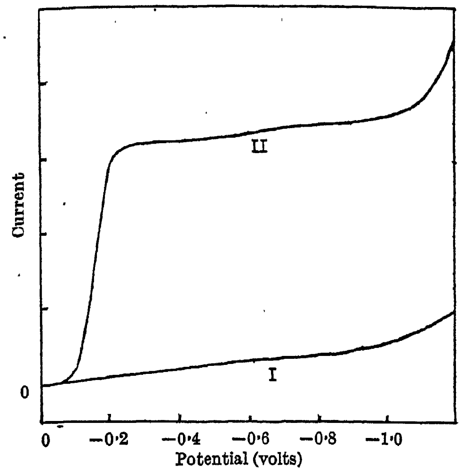

Fig. 3. CURRENT-VOLTAGE CURVE FOR ANTIMONY. I, 0·0001 *M* SODIUM QUINQUEVALENT ANTIMONY GLUCONATE; II, 0·0001 *M* SODIUM TERVALENT ANTIMONY GLUCONATE.

technical gases, activated sludge and lake water, and for studying the photosynthesis- and respiration-rates of micro-organisms.

The polarograph is of considerable theoretical importance for the study of oxidation-reduction systems. An ideal example of a reversible reduction at the dropping-mercury electrode is given by quinhydrone and its components. In a well-buffered solution, the step due to the reduction of benzoquinone has the same characteristic half-wave potential as the step due to the oxidation of hydroquinone. If quinhydrone is examined, one half of the curve represents an oxidation of hydroquinone at the mercury anode, while the other half represents a reduction of benzoquinone at the mercury cathode. An oxidation-reduction system is thermodynamically reversible if identical polarographic half-wave potentials are obtained for the reduction of the oxidant and oxidation of the reductant. As would be expected, values for the oxidation-reduction potentials[9,10] of such systems determined polarographically are in good agreement with those obtained by the classical methods.

The electrolytic examination of most organic substances involves reactions which are not thermodynamically reversible, since products are formed which cannot be oxidized or reduced to give the starting material at the same electrode potential. The reductions of aldehydes, ketones, unsaturated acids and nitro-compounds belong to this group.

The polarographic behaviour of the various vitamins which contain reducible groupings has been studied extensively. Aneurin (thiamin; vitamin $B_1$), riboflavin, nicotinic acid, pantothenic acid, ascorbic acid (vitamin C), α-tocopherol (vitamin E) and vitamin K can be determined in pure solution, but further work is required before they can be estimated in the presence of other reducible substances. Cholesterol[11] and other constituents of fish liver oils interfere with the polarographic determination of α-tocopherol. The mechanism of the riboflavin step has been investigated further by Brdička and Knoblock[12].

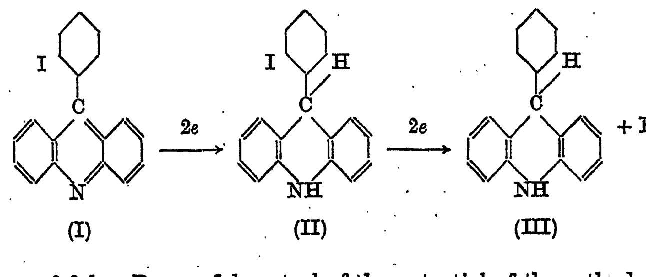
The dropping-mercury electrode can be used for the determination of certain sex hormones[13]: α : β-unsaturated keto-steroids (for example, testosterone, progesterone, corticosterone, and desoxycorticosterone) are reducible, while the 17-ketosteroids (for example, androsterone and *iso*androsterone) are not. Nevertheless, the latter may be condensed with excess Girard reagent *T* (trimethyl acethydrazide ammonium chloride) to yield derivatives which have an electro-active molecule. The steps are well defined and can be used for the determination of the different ketosteroids in urine extracts; but unfortunately the method cannot be applied to mixtures of ketosteroids as the individual steps are too close together.

Kolthoff and his colleagues[14] have started a polarographic investigation of the sulphonamides with the view of testing theories as to their mode of action. Oxidation products of sulphonamides[1] such as *p*-hydroxylaminobenzenesulphonamide, *p* : *p'*-azoxybenzenesulphonamide and *p*-nitrobenzenesulphonamide are electro-reducible at the dropping-mercury electrode.

In addition to reversible and irreversible direct reductions, catalytic reductions may also occur at the dropping-mercury electrode. Brdička[15] observed that if sulphur-containing proteins were reduced in a buffered cobalt or nickel solution, a large double step formed. Cystine and cysteine behaved in the same way, but only gave a single large step. Since these special steps were not obtained in the absence of cobalt and nickel, Brdička concluded that the hydrogen evolution from the sulphhydryl groups is catalysed by the metals.

The curious behaviour of these catalytic steps attracted considerable attention. When blood proteins from different individuals were examined, it was noticed that serum from cancer patients gave a much smaller protein double step than that resulting from the serum of normal patients. This phenomena appeared to offer great possibilities for the diagnosis of cancer, but unfortunately it has since been found[16] that sera from patients suffering from pneumonia and arthritis show a similar effect.

The polarographic method may be used in synthetic organic chemistry to select the best conditions for carrying out electrolytic preparations at controlled potentials. Lingane, Swain and Fields[17] found that the reduction of 5-(*o*-iodophenyl)-acridine (I) proceeds in two stages, first to 5-(*o*-iodophenyl)-dihydroacridine (II) and then to 5-phenyl-dihydroacridine (III) with elimination of iodine, the reduction potentials at the mercury cathode of the two stages being separated by about 0·3 V.



By careful control of the potential of the cathode, it was possible to prepare either compound (II) or (III) in a high state of purity and in almost quantitative yield. The method should be of particular value whenever the selective oxidation or reduction of only one out of two almost equally reactive groupings in a molecule is required.

There is no room in this short account of recent research with the polarograph to deal with the rapidly growing field of amperometric titrations, which has been developed so extensively by Kolthoff and his collaborators at the University of Minnesota. Nevertheless, it is hoped that sufficient material has been incorporated to indicate the versatility of the polarograph and the general usefulness of polarography.

## DIETARY STUDIES IN GREAT BRITAIN

THE lecture theatre at the London School of Hygiene and Tropical Medicine was well filled for the second part of the conference arranged by the Nutrition Society on "Budgetary and Dietary Surveys of Families and Individuals" held on May 20; and it remained full, practically to capacity, until the end. That there is an extraordinary and intense interest in the problems of nutrition, awakened largely as the result of the War, but drawing on the experience of those trained in nutritional problems during the War of 1914–18 and since, was manifest. Every paper was followed with close attention, though humour, conscious or unconscious —one member spoke of his "cooked figures"—received its reward.

The first part of the conference, held on February 5 (see *Nature*, March 11, p. 306), dealt with the practical and theoretical problems involved in making dietary surveys; the accuracy and the statistical validity of such surveys and the interpretation of results. The second part of the conference dealt with the results of surveys obtained by the individual, the group, the reminiscent and housekeeping methods, though no budgetary surveys were given. It was clear that each protagonist was satisfied with the method he adopted and inclined to doubt the validity of the other methods. Also it was clear that the Nutrition Society is bowing its knee to the Dagon of statistics, possibly with too little care to see that the figures before 'manipulation' approximate to reality. However that may be, there were gathered together a large number of people willing and able to bring their scientific ability to bear on the problem of feeding the people in the optimal way.

The chairman, Dr. J. Hammond, opened with almost the fewest possible remarks, and called on Miss E. M. Widdowson and Dr. R. A. McCance (Department of Medicine, University of Cambridge) for their paper on dietary surveys by the individual method. The paper was based by Miss Widdowson on the dietary surveys of more than a thousand middle-class children in the years before this War, on some recent surveys, and on figures already reported for 63 men and 63 women. The problem was to obtain the figures and then to 'manipulate' them. The figures were obtained by the weighing of foods at table by intelligent, though not necessarily laboratory-trained, people. In calculation, tables for cooked, not raw, foods were taken. When results from tables were compared with actual laboratory analysis, there was not much difference, except in calcium and iron. The calcium and iron were higher in analysis as the result of tap-water cooking and contamination of the foods with iron from knives, saucepans and mincing machines. A week's survey is sufficient, but there are huge daily fluctuations in intake. The results obtained from the thousand children show almost as great a deviation from the mean as those of the 63 men and 63 women. At any age, one child in that age group might be eating twice as much as another in that same group. A boy of two years might be eating more of some dietary constituent than one of seventeen; protein and vitamin $B_1$ increase with age, calcium and vitamin C remain constant or fall as the age increases. Boys of fourteen ate four times as much meat as those of four, but only twice as many potatoes. Family and individual dietaries should be carried out side by side. If a family is getting its 'right' quota, but father is taking 4,500 calories, then the rest of the family (say mother and son) are being underfed.

Prof. V. H. Mottram (King's College of Household and Social Science, University of London) agreed that the man-value story has proved useless and should be buried. He believed that all this work points back to the calorimeter. The daily fluctuations cancel out in a group, so that a day's intake is sufficient guide. Prof. J. R. Marrack (London Hospital Medical School) asked what was done about made dishes which might vary in cooking, and suggested that the histories of these children who over- or under-fed should be followed up.

Dr. F. C. Happold (University of Leeds) said that the determination of expenditure of energy by medical students agrees with both weighed and estimated food intakes with small standard deviation. Others asked whether the readers' figures had been analysed statistically and whether colds did not alter food intake. Mr. A. L. Bacharach (Glaxo Laboratories) pointed out that what children eat is not necessarily a measure of what they ought to eat. In reply, Miss Widdowson admitted that made dishes are the nightmare of dietary surveys, minor ailments do influence food intake, though minor ailments are part of ordinary life and that her figures had been submitted to statistical manipulation. Dr. Gertrude Wagner (Wartime Social Survey) gave the results of surveys of methods used in preparing and cooking food. These investigated the ways in which people in different parts of England buy and prepare vegetables. 2,600 interviews were made. 100 per cent of families take potatoes, 90 per cent 'greens', 80 per cent carrots but only 47 per cent leeks. Higher income classes eat more vegetables than lower, but women at work often cook as many vegetables as those with more leisure. Only the well-to-do use

methods advocated by the 'kitchen front' or taught in the schools. Age seems to make no difference. Food 'education' seems to have little effect.

Mrs. B. Callow (School of Biochemistry, Cambridge) referred to the recent publication, "Food Consumption Levels", and said that we in Great Britain apparently receive food which, before cooking, yields sufficient vitamin C. The U.S. National Research Council recommends 75 mgm. a day for men, and a restricted standard of 50 mgm. In Great Britain, we obtain at least 85 per cent of one vitamin C from vegetables in war-time, and cooking may result in lowering that 75 mgm. below safety-level.

Later speakers directed attention to the fact that the freshness of vegetables affects the vitamin C, though wilting affects spinach more than it does the Brassicas. The amount of ascorbic acid left in vegetables after boiling depends more on the final amount of the boiling water than on its volume to begin with. Sodium bicarbonate does not influence the loss during boiling, but alkalinity of the vegetable when dished up accelerates the rate of oxidation of ascorbic acid after the dishing up. Officials from the Ministry of Food find that vitamin C estimations in cooked food are often below those calculated from tables even though the method of preparation is thoroughly known, and are pessimistic about the use of tables for estimating individual intakes of vitamin C. Shredding vegetables does not markedly alter their vitamin C content. Miss M. Olliver gave an account of the laboratory assessment of nutritive value of meals which Dr. G. N. Jenkins, Dr. L. W. Mapson and she had carried out. If sampling is conscientious, and bulking and mixing of the samples is adequate, and precautions are taken to prevent oxidation of ascorbic acid, the results of estimations are not so very different from those found by calculations from tables; but Miss Olliver stressed that anyone using tables for calculating the ascorbic acid intake must have considerable experience of the methods used in cooking and serving vegetables. She also demonstrated an admirable American machine for mixing samples of foods.

Dr. C. P. Stewart (Royal Infirmary, Edinburgh) opened the discussion on this communication. He said that the agreement between calculation and observations on ascorbic acid in foods is not bad. A hospital he had investigated reduced the figure of ·8 mgm. per 100 gm. of potatoes down to 0·8 mgm. 'as served'.

Dr. Yudkin (R.A.F.) pointed out that the physiological state of members of an institution can be used to estimate the value of the diet given. After six months, the hæmoglobin figure for the W.A.A.F.s rose from 95 on the Haldane scale to 102. Dark adaptation is normal in the R.A.F. and W.A.A.F. The caloric value of the diet is more than 3,000 Calories a day, and though only 40 per cent of the protein in the diet is animal protein its biological value is that of milk protein.

The afternoon was devoted to the data obtained from analyses of institutional diets. Miss E. M. Langley (Board of Education) spoke of school meals. The Oslo meal is popular with children but takes long to eat and therefore is unpopular with the staff where quarters are cramped. 1,000 Calory-meals are not difficult to produce, but cooks are reluctant to use concentrated foods. The target is 3,000,000 meals a day. At the outbreak of the War, 250,000 were served. To-day, the figure is 1,500,000 despite cramped quarters, absence of kitchens and dining-rooms. There is no doubt that school meals and school milk improve health and physique, and this service is becoming an integral part of the educational system of Great Britain.

Dr. M. Pyke (Ministry of Food) gave an account of investigations of factory canteen meals and service, and showed that the effect of a small change of the shift-time alters the spacing, times and natures of meals taken by work-people enormously. The pattern of the meals, the size and quantity of the nutrients taken varies immensely with a minor shift in hours and by no means in a predictable manner. There is a big variation, too, in the energy value of the foods taken by different workers, but there is considerable correlation between it and their work. Between different parts of the country, even in the same industry, there are marked differences in tastes. The coal miners in Wales eat cheese, the Durham miners refuse it. Are traditional methods of feeding justified, and should we pay attention to prejudices?

Dr. A. Lyall (University of Aberdeen) reported on hospital diets in three different hospitals. It was found that food brought in by friends of patients varied from 200 to 800 calories per day. As 40 per cent of patients in one hospital were on a light diet and 32 per cent on special diets, this extra food represents a marked interference with the feeding of the patients. It is doubtful if it should be allowed.

Miss M. C. Broatch (King Edward's Hospital Fund), who has had much experience in the feeding of school children, maintained that the Oslo type of meal should be preferred. The children have to sit longer to masticate it and get a rest during dinner-time. But often children are hurried through meals because, owing to inadequate accommodation, there have to be two sittings in the dinner hour. She said that no survey yet showed meals giving 1,000 Calories, and so children cannot be getting what the Ministry of Food recommends. Serving raw vegetables in the Oslo meal makes the 1,000-Calorie meal still more unlikely. Only by giving suet puddings can the 1,000-Calorie meal be attained.

Meals are best in institutions where there is a buyer, and food is not bought on contract. To serve dietetic meals in hospitals needs a reorganization of staff, for generally the cook is untrained, the steward has no experience and the housekeeping sister has had no training in general catering. All caterers ought to be cooks. Food should not be brought in by friends. The proper feeding of patients in hospitals is part of the treatment. A very weak spot is the delay between kitchen and ward and ward and patient. Meals in transit lose much of their value.

A Cardiff worker reported that school meals sometimes reach Miss Langley's figure. But the average for vitamin C in a large number of canteens throughout a year was 25 mgm. ascorbic acid a meal. It is almost impossible to get higher figures with the expenditure allowed and the equipment available. Children cannot, or will not, eat enough watercress to give 25 mgm. ascorbic acid—they take 8–10 gm. a meal instead of about 100 gm. One third of the children get no vitamin C at any other meal.

Dr. Magee (Ministry of Health) pointed out that Dr. Milligan of Glossop was using the 'Oslo' meal years before we ever heard of it in Britain. He questioned if there is much deficiency disease among children in Great Britain. When 5,000 children were investigated, no single case of scurvy was discovered; but riboflavin deficiency is sometimes observed. One reason for the poor diet in hospitals is that caterers

do not know the priorities they are entitled to. They should be able to serve 131 gm. protein a day, of which 78 gm. could be animal protein. Hospitals often underdraw their rations of meat, dried eggs and milk.

The general impression produced by all the discussions was that though an enormous amount is known about the way people should be fed, there are not the trained personnel, equipment, or space to do the work adequately.

The Society passed a resolution, moved by Sir Joseph Barcroft, recommending that the Committee of the Society investigate the possibility of carrying out direct calorimetry experiments.

## OBITUARIES

### Mr. W. L. Sclater

WILLIAM LUTLEY SCLATER was born on September 23, 1863, and died through enemy action in June. He was the eldest son of Dr. P. L. Sclater and was educated at Winchester, and afterwards at Keble College, Oxford, where he studied under Moseley and Hickson, taking his M.A. with first-class honours in natural science in 1885. In the following year he worked under Ray Lankester in London, and also made a short collecting trip to British Guiana, whence he brought back live specimens of Peripatus.

In 1887 he acted as demonstrator to Sedgwick at Cambridge, and in August was appointed deputy superintendent in the Indian Museum at Calcutta. There he remained until 1891 and, in addition to other work, prepared Part 2 of the "Catalogue of Mammalia in the Museum", also lists of the birds' eggs, snakes and Batrachia. Towards the end of 1891 Sclater returned to England and joined the staff of Eton College as one of the science masters. In the latter part of 1895 he was appointed director of the South African Museum at Cape Town; but before proceeding there he married on February 1 Charlotte Seymour, daughter of W. P. Mellen of Colorado Springs. A new wing had just been completed for the South African Museum, and Sclater removed and rearranged the collections and also reorganized the staff. He widened the scope of the Museum and started the *Annals of the South African Museum*. The planning and publication of the "Fauna of South Africa" was principally due to Sclater, who acted as editor and wrote the two volumes on mammals. He was responsible for Vols. 3 and 4 of the birds after Dr. Stark's death in Ladysmith. This work, although now out of date, is still of value to the student of the South African fauna.

In 1906 Sclater and his wife returned to England via Mombasa, Victoria Nyanza, Khartoum and Cairo, which was quite an undertaking in those days. Shortly after his return Sclater was invited by his wife's uncle, General W. J. Palmer, to develop and enlarge the museum recently established in connexion with Colorado College. After General Palmer died in 1909 Sclater gave up his post and returned to London, where he took up residence at 10 Sloane Court, and began his long connexion with the Bird Room of the British Museum. Besides continuing his studies on African birds and publishing important papers he became the recorder for the section of Aves of the *Zoological Record*. This he continued to the time of his death, and at different times was responsible for other sections, including Mammalia and Crustacea. From 1921 until 1937 he was general editor and introduced many important changes into the arrangement of the *Record*. In 1912 he published a "History of the Birds of Colorado".

After the retirement of Mr. Ogilvie Grant in 1918, Sclater was entrusted with the temporary care of the ornithological collections in the British Museum up to the appointment of Dr. P. R. Lowe in 1919. During that time he rearranged part of the collection and prepared a manuscript "Catalogue of the Birds of Prey".

The Sclaters travelled much on the Continent and in North Africa and in 1919 made a trip round the world, including visits to many of the principal museums in the United States, where they renewed many old friendships. On their return Sclater commenced his great work, the "Systema Avium Æthiopicarum", which was published in 1924. This book is indispensable to all students of African birds. He also edited from Sir Frederick Jackson's manuscript "The Birds of Kenya Colony and Uganda Protectorate" (1938).

Sclater succeeded his father as editor of the *Ibis* in 1913, and for seventeen years held that office. He was president of the British Ornithologists' Union from 1928 until 1933, and in 1930 was presented with the Salvin-Godman Gold Medal for his services to ornithology.

In addition to birds Sclater had many other interests, including family history, publishing in 1922 a delightful volume of an ancestress Eliza Draper, better known as 'Strene's Eliza'. At the time of his death he was honorary secretary of the Royal Geographical Society and had held that office since 1931. Owing to his long connexion with the *Zoological Record*, Sclater had a very wide knowledge of literature, which he readily placed at the disposal of others. This knowledge was not confined to modern works, for he was a recognized authority on the older writers. He was a great walker, and few knew the country around London better than he.

His death is a great loss to his many friends, and in the Museum we will miss seeing that tall, slightly stooping figure walking through the galleries on his way to and from the Bird Room.

N. B. KINNEAR.

### Dr. I. Markovič

IT has recently been learned that Dr. Ivan Markovič, a former Czechoslovak Minister of Education and sometime editor of the Bratislava literary and scientific periodical, *Prudy*, died in a German concentration camp some months ago. Markovič was born at Myjava in Slovakia in 1888 and was in Russia at the outbreak of the War of 1914–18. He eventually became a member of the Czechoslovak National Council and held various diplomatic and Government posts after the formation of the Czechoslovak Republic in 1918.

WE regret to announce the following deaths:

Prof. Carl Jakobj, emeritus professor of pharmacology at Tübingen, aged eighty-seven.

Dr. L. E. Shore, O.B.E., formerly lecturer in physiology and junior bursar of St. John's College, Cambridge, on July 27, aged eighty-one.

Dr. J. N. Sugden, senior lecturer in inorganic chemistry at the Imperial College of Science and Technology, in July, by enemy action.

# NEWS and VIEWS

## Swedish Anthropological and Geographical Society: Award to Prof. L. von Post

THE highest distinction of the Swedish Anthropological and Geographical Society, the Vega Medal, has just been awarded to Prof. Lennart von Post, of Stockholm, for his outstanding contributions to the development and application of the methods of pollen analysis. It is Prof. von Post above all others who, by his clear vision and indomitable energy, both perfected and popularized the systematic analysis of the sub-fossil pollen content of lake- and peat-deposits. Speaking at the meeting when the award was made, Prof. von Post emphasized the manner in which pollen analysis studies from all parts of the world—Tierra del Fuego, New Zealand, North America, North China, as well as Europe—showed a similar post-glacial climatic drift, first of increasing temperatures, then through a period of severe heat and drought, and finally a recession to the climate of to-day. He visualized a forthcoming phase of international co-operation in pollen analysis work in systematically selected areas all over the world, by means of which we should resolve the general pattern of the cyclic climatic history of the world in the period since the last ice age. May Prof. von Post's vision be again rewarded by scientific advances comparable with those he has already accomplished.

PROF. LENNART VON POST (LEFT) RECEIVING THE VEGA MEDAL OF THE SWEDISH ANTHROPOLOGICAL AND GEOGRAPHICAL SOCIETY FROM THE CROWN PRINCE OF SWEDEN.

## Co-operative Research in Industry

IN reply to a question from Lord Barnby in the House of Lords on August 1, Lord Templemore re-affirmed the great importance attached by the Government to co-operative research as a means of developing to the full the use of the industrial resources of Great Britain, a vigorous export trade and a higher standard of living. While the Cotton Industry Research Association, which receives a substantial contribution from the Cotton Board, set up under the Cotton Industry Act, is the only research association which is not supported solely by voluntary contributions or voluntary levies, apart from the Government grant, recently several industries, including the wool industry, have expressed themselves in favour of statutory powers of one sort or another, including the collection of money for research by means of a levy on the whole industry, and research associations are now much more inclined to welcome an enabling bill. Lord Templemore said he was authorized to state that the Government will be prepared to consider sympathetically the introduction of enabling legislation for this purpose, if there is sufficient demand for it from industry, and that the matter will be discussed with industry in the coming months in connexion with post-war plans. The Government would also wish to be satisfied whether there are other proper objects connected with the furtherance of the export trade or of industry's efficiency generally for which a statutory power to collect money might be desirable.

## Human Factors in Industrial Output

IT is sometimes forgotten that output results from human activity and that therefore the amount will be dependent on many factors, of which it has been shown that the number of hours worked each week is one. There is abundant evidence that excessive hours result in diminished output. When, however, hours are relatively reasonable, can it be argued that a further reduction will increase the output ? A recent report ("A Study of Variations in Output." By S. Wyatt and others. Emergency Report No. 5 of the Industrial Health Research Board. (London: H.M. Stationery Office, 1944.) 4*d*. net.) analyses some of the factors which had measurable effects on output. Study of the output records of a number of factories showed a striking variability. Some of the chief causes were: (*a*) changes in the type or design of the product; (*b*) mechanical difficulties and machine breakdown; (*c*) variations in the quantity and quality of the materials used; (*d*) progressive improvements in the methods or conditions of work; (*e*) changes in the type and lay-out of machines; (*f*) personal factors such as dissatisfaction with the methods or rate of payment, and occasional friction between the management and the workers.

The effects of the shorter hours of work were in most groups obscured by one or other of the above factors; but, when these were absent, reduction of hours from about an average of 60 to 55 a week for men, with a corresponding decrease for women, had a favourable result on the output. Absenteeism also tended to decrease as the weekly hours of work decreased. The results suggest that there is need for more research work to determine under what general or specific conditions changes of design, for example, have unfavourable effects on output, and the relative effectiveness of the chief causes of variations in output. Machines should be made for men, not men forcibly adapted to machines, which means careful physiological and psychological study.

## Research and Development in Scotland

A MEMORANDUM, "Chemical Research and Development in Scotland", by R. H. S. Robertson issued as *Bull.* No. 3 (March 1944) by the Scottish Reconstruction Committee urges the need for chemical and physical research and development in Scotland, stressing particularly housing research and research in relation to hydro-electricity, the lack of trained personnel in Scotland and the inadequacy of present facilities. The memorandum suggests the formation of a Scottish raw materials department under the Department of Scientific and Industrial Research,

with a wider field of activities than a development branch of the Geological Survey which would be restricted to the study of minerals, including peat. This department should co-ordinate every stage of development from survey to production and carry out the experimental work which existing organizations are not equipped to do, as well as serve as an institution for giving additional training to the technical men who will develop and eventually run the new industries. Apart from its references to seaweed and peat, the memorandum gives very little indication of what materials call for the creation of a new department to investigate Scottish resources. Neglect of those resources will be readily admitted, but it is not clear from this memorandum why their investigation and development could not be undertaken as part of the general national research effort—why, for example, separate Scottish research into housing is required.

## Astronomy and the Struve Family

On the occasion of the award of the 1944 Gold Medal of the Royal Astronomical Society to Prof. Otto Struve, the president of the Society, Prof. E. A. Milne, reviewed the astronomical work of the Struves, which has been recognized by four awards of the Gold Medal to the family in 118 years—once in each generation (*Mon. Not. Roy. Astr. Soc.*, **104**, 112; 1944). Wilhelm Struve, founder of the Pulkovo Observatory, received the Gold Medal in 1826 for his work in discovering and measuring double stars. His son, an earlier Otto Struve, was awarded it in 1850 for a paper on "The Determination of the Constant of Precession with respect to the Proper Motion of the Solar System". The third medallist was Hermann Struve, uncle of the present holder, who gained the award in 1903 for his monumental work on the satellites of Saturn. This year's award goes to Prof. Otto Struve, director of the Yerkes and McDonald Observatories, and great-grandson of Wilhelm, for his observation and interpretation of the spectra of stars and nebulæ. Prof. Milne reviewed this work in some detail, and pointed out that the present medallist has followed the family tradition in founding a new observatory, and has exceeded it in directing not merely one but simultaneously two great observatories. In his power of execution of new projects, in the width and generality of the problems he has selected and attacked, and in the brilliance of his solution of these problems, said Prof. Milne, Otto Struve has worthily carried the family fame in a new branch of astronomy to a new continent, and made good.

## Telepathy in Psychoanalysis

Dr. H. J. Ehrenwald, formerly of Prague, has directed attention to the possibility of telepathy in the psychoanalytic situation (*Brit. J. Med. Psych.*, **20**, Pt. 1; 1944). It is well known to psychical researchers that since Freud mentioned this factor in his new series of introductory lectures, his pupils have obediently followed him and are themselves now at pains to discuss the question in relation to their own patients. In this paper, Dr. Ehrenwald extends these observations not only regarding telepathy from patient to analyst but also from analyst to patient. He mentions some of Freud's own cases, including the famous case of his patient, Mr. P., which Freud thought to be very suggestive, but which few psychical researchers would regard as worthy of serious consideration. What is, however, of more interest in Dr. Ehrenwald's paper is his obvious anxiety to warn his colleagues of the possibility of telepathy occurring during sittings with their patients, and the implications which can be derived from it. From the point of view of the psychical researcher this attitude is somewhat diverting, since for so many years psychoanalysts have declined to learn what parapsychologists could have taught them and now, having become almost convinced through Freud's influence that telepathy exists, present examples of it which exhibit so many sources of error that it is clear that they still have little appreciation of the problems on which they write. If Dr. Ehrenwald's paper disturbs still further their complacency, it will have performed a useful service.

## Chinese Journal of Agricultural Science

The British Council made a very happy choice in selecting Dr. J. Needham for its scientific mission in China. He has been indefatigable in promoting scientific work in that part of the country which remains in Chinese hands and in his efforts to keep British scientific workers informed about Chinese work. Since the outbreak of the War, most of the scientific journals in China have been discontinued, and in consequence those keen spirits that still go on with their scientific studies have their difficulties increased by the lack of any means of publication. A new journal has now been started by the Ministry of Agriculture and Forestry at Chungking, and the first issue is to hand. Among other papers are two on inheritance in wheat. One on dwarfness deals with the complex ratios obtained in counts of the $F_2$ progenies of the varietal crosses made in 1939; seven factors are assigned, of which three are complementary, three are duplicates of these and one is an inhibitor; the combinations necessary for dwarfness are discussed. The other paper is a mathematical discussion of Japanese data on the pentaploid hybrids of wheat. Trials are recorded of the Winogradksy Azotobacter plaque method for estimating potash and phosphate deficiencies in soils: this was found to be rapid and easily worked and seems likely to prove very valuable if its indications are borne out in practice. Other papers deal with the extraction of nicotine from tobacco leaves; the orange maggot (Tetradacus sp.); and a possible vermicidal plant, *Tripterygium wilfordii*. The papers are in Chinese, but with summaries in English. We wish the new journal all success.

## University of London

Mr. T. H. Marshall has been appointed as from October 1 to the University chair of social institutions tenable at the London School of Economics. Since the beginning of the War he has worked in the Foreign Office Research Department, as head of the German Section since the autumn of 1940, and as deputy director since the spring of 1943.

Mrs. Barbara Wootton has been appointed as from October 1 to the University readership in social studies tenable at Bedford College. Since 1927 she has been director of studies for tutorial classes in the University and has acted as visiting lecturer in the Department of Social Studies at Bedford College for some years.

The title of professor of chemistry in the University has been conferred on Dr. E. E. Turner, in respect of the post held by him at Bedford College.

## Liver Ribonucleic Acid

IT has previously been shown[1] that mammalian tissues contain, in addition to nuclear desoxyribonucleic acid (thymonucleic acid), appreciable amounts of pentose nucleic acid, which appears to be mainly a cytoplasmic constituent[2]. Liver tissue, for example, is known to contain both a desoxyribonucleic acid similar to the thymus nucleic acid[3] and a pentose nucleic acid[1]. The latter has now been isolated from the liver tissue of the sheep. The finely minced liver is dehydrated with ethanol and the nucleic acids extracted with 10 per cent sodium chloride. They are precipitated with ethanol, and the barium salts fractionated by the method used by Jorpes[4] for the pentose nucleic acid of the pancreas. The pentose nucleic acid is finally purified by precipitation from glacial acetic acid. The material so obtained is free from protein and from desoxyribonucleic acid. It is similar to yeast ribonucleic acid in its pentose content and in its absorption spectrum. Its contents of purine and easily hydrolysable phosphorus are consistent with a tetranucleotide structure with equimolecular amounts of purine and pyrimidine. It appears to differ, therefore, from the pentose nucleic acid of the pancreas, for which a pentanucleotide structure has been suggested[4].

From the hydrolysis products obtained by the method of Bredereck and Richter[5], we have prepared the pentose and identified it as ribose by the *p*-bromophenylhydrazone, which melted at 168–169°. This melting point showed no depression when the derivative was mixed with a sample of the *p*-bromophenylhydrazone prepared from pure *d*-ribose. The nucleic acid can therefore be correctly designated 'liver ribonucleic acid'. Gulland and Barker[6] have recently proved conclusively that the pentose of yeast ribonucleic acid is *d*-ribose, and have shown that small amounts of *l*-lyxose are also present. The amounts of liver ribonucleic acid so far available have been too small to enable tests for lyxose to be made.

Liver ribonucleic acid acts as a substrate for crystalline ribonuclease. When sections of liver tissue, fixed, embedded and mounted, are stained with toluidine blue, both nuclei and cytoplasm take up the stain. If the sections are treated with ribonuclease in the manner employed with other tissues[7], and then with toluidine blue, the nuclei alone stain. The liver ribonucleic acid, therefore, probably occurs in the cytoplasm, in which it may be present in the form of phospholipin-ribonucleoprotein complexes in the particulate components (mitochondria[8], secretory granules[9], microsomes[10]). These complexes are known to contain a nucleic acid of the pentose type which is presumably identical with the ribonucleic acid which we have isolated.

In confirmation of the work of others[11], we have found that the total nucleic acid concentration in the liver of the rat rises on fasting, although the liver weight relative to the body weight falls. Dry powders of rat livers from which acid-soluble and lipoid phosphorus had been removed, contained $554 \pm 10{\cdot}7$ mgm. residual phosphorus per 100 gm. in the case of fed animals and $583 \pm 20{\cdot}5$ mgm. in the case of fasted animals. Of this residual phosphorus, $75{\cdot}3 \pm 2{\cdot}33$ per cent in the fed animals and $66{\cdot}0 \pm 2{\cdot}86$ per cent in the fasted animals was accounted for as ribonucleic acid phosphorus; $17{\cdot}6 \pm 0{\cdot}59$ per cent in the fed animals and $20{\cdot}2 \pm 0{\cdot}84$ per cent in the fasted animals was accounted for as desoxyribonucleic acid phosphorus. The fall in ribonucleic acid and the rise in desoxyribonucleic acid on fasting were both statistically significant. These results would be consistent with the disappearance from the cytoplasm of particulates containing ribonucleic acid, and with the loss in phospholipin and in nucleoprotein observed in the livers of rats fasted or placed on a protein-poor diet[12].

## Effect of Dietary Protein on Liver Cytoplasm

IT is well known that the protein content of the liver can be lowered by fasting or by feeding a low-protein diet and raised by feeding a high-protein diet. The question arises: Is the protein stored in the liver as is glycogen, or is it built into the structure of the cytoplasm? Since the evidence so far available on this point is equivocal, it was decided to correlate, under various nutritional conditions, the protein content of the liver with other cytoplasmic constituents, namely, phospholipin and nucleic acid.

In a previous communication[1] it was shown that fasting caused a loss in the protein as well as the phospholipin and nucleic acid contents of the livers of rats. Similar changes are obtained if the animals are placed either on a protein-free diet or given protein deficient in one or more essential amino-acids. On the other hand, a high protein diet causes an increase in the protein, phospholipin and nucleic acid contents of the liver. There is no change in the number of liver cell nuclei (Table 1).

If the protein content of the diet is varied, the relative concentrations of protein and phospholipin remain remarkably constant, while that of nucleic acid rises gradually with falling protein intake (Table 2). This latter fact is probably due to there being no, or only little, loss in nuclear material which, although in mass much smaller than cytoplasm, has a much higher concentration of nucleic acid than cytoplasm. This interpretation is supported by the recent findings[2] that the ratio of ribonucleic to desoxyribonucleic acid is lower in livers of fasted rats than in those of fed rats. The relative

| 85 per cent casein | 770 | 124 | 55 | 603 |

* Female hooded rats 4 months old were given 16 gm. of the diets daily for one week. The diets contained 2 per cent agar, 3 per cent salts, 10 per cent lard, 25 per cent sucrose and varying quantities of protein and starch. Vitamins A, D and E were given in the usual manner, and the vitamin B complex in the form of dried yeast or of a mixture of aneurin, riboflavin, pyridoxin, calcium pantothenate, nicotinic acid, inositol and choline chloride, supplemented by liver concentrate.

protein concentration shows a slight rise when the protein intake is above optimum requirements.

The constituents of liver cytoplasm which contain protein, phospholipin and nucleic acid are the chromophilic substance of the cytoplasm and the mitochondria[2]. A recalculation of Claude's results on rats' livers yields as approximate composition of the chromophilic substance (on a dry glyceride-free basis) 60 per cent protein, 33 per cent phospholipin and 7 per cent nucleic acid; and of the mitochondria 74 per cent protein, 15 per cent phospholipin and 8 per cent nucleic acid. The nucleic acid is ribonucleic acid[2,3]. The nuclei contain 22 per cent desoxyribonucleic acid[4]. Since the phospholipin content of the whole liver cell is considerably lower than that of the chromophilic particulates, it would appear that not only the relative concentration of the chromophilic lipoprotein–nucleic acid complex but also that of the interparticulate protein, which is almost free from phospholipin[2], remain constant. In other words, the changes in the protein contents of the livers observed after fasting and diets low or high in protein are due to changes in the cytoplasm content of the liver. This phenomenon is of greater physiological and pathological significance than would be a simple storage of protein, in that many of the enzymatic activities of the liver cell are associated

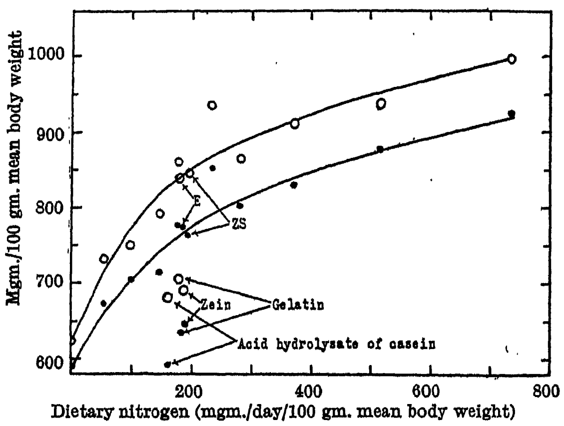
with its cytoplasmic particulates[2]. It has also been found that the arginase activity of the liver is dependent on the quantity of dietary protein[5]. These facts are of importance in view of the damaging effects which low-protein diets have on liver function[6].

Rats on a protein-free diet lose 15 per cent of their initial liver cytoplasm on the first day, 7 per cent on the second day, 5 per cent during the period from the second to the seventh day, and another 5 per cent during the second week. It appears that about 20–25 per cent of the liver cytoplasm of animals fed sufficient quantities of protein is very easily and rapidly lost, and it is suggested this fraction be called 'labile liver cytoplasm'. This term, however, is not meant to indicate a chemical distinction between the labile and the remaining cytoplasm.

The histological diagnosis of the loss of cytoplasm is complicated by the fact that the total weight of the liver may undergo considerable changes and is, at least so far, only possible in livers which have lost considerable quantities of their cytoplasm, namely, 20–25 per cent. However, the livers of the rats given the low protein diets remain almost constant in weight and show a diminution of their stainable cytoplasm and mitochondria. An apparent



EFFECT OF VARYING THE DIETARY PROTEIN ON THE CYTOPLASM CONTENT OF THE LIVER.

○—○, Non-glycogen non-lipin solids. ●—● Protein + phospholipin + nucleic acid. The dietary protein was casein except where specially marked, thus: *E*=diet containing 21·5 per cent egg albumin; gelatin=diet containing 18 per cent gelatin + 8 per cent yeast; zein=diet containing 18·5 per cent zein; *ZS*=diet containing 18·5 per cent zein supplemented with 2 per cent *l*-tryptophane and 5 per cent *l*(+) lysine dihydrochloride; acid hydrolysate of casein=diet containing 22·4 per cent acid hydrolysate of casein, deficient in tryptophane.

vacuolization takes place, probably due to the largely increased glycogen content of these livers. In fasted animals, due to a decrease in liver weight, there is chemically an increase in the concentration of cytoplasmic substance although the absolute quantity of cytoplasmic substance decreases. Histologically, small cells are found which stain intensely. These findings are in good agreement with those reported by Elman, Smith and Sachar[7].

The changes in cytoplasmic substance may also be determined, with a high degree of approximation, by estimating the non-glycogen non-lipin solids. This method may lend itself to a rapid assessment of the biological values of proteins (see accompanying graph).

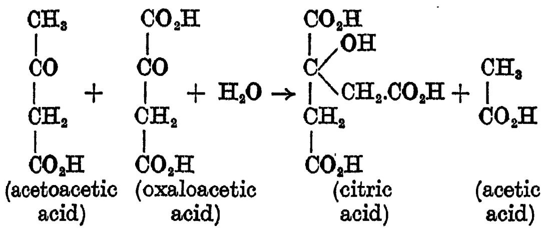
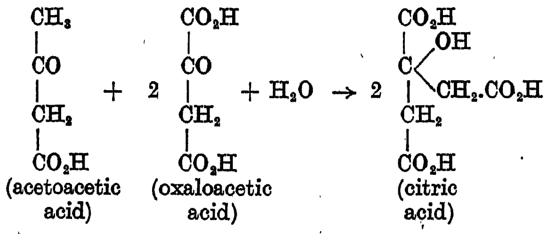
## Metabolism of Acetoacetic Acid in Animal Tissues

BREUSCH[1] assumes that acetoacetic and oxaloacetic acids form citric acid in animal tissues according to the reaction:



Wieland and Rosenthal[2], apparently independently, arrive at a similar view. They suggest that the following reaction occurs in kidney and heart:



Both schemes are based on the observation that under certain conditions more citric acid is obtained from oxaloacetic and acetoacetic acids together than from oxaloacetic or acetoacetic acid alone. The importance of the schemes lies in the fact that they outline for the first time a mode of breakdown of acetoacetic acid in animal tissues, a problem which, in spite of many efforts, previous workers have failed to unravel.

Experiments on sheep heart and sheep kidney, although they confirm the observation that acetoacetic acid can increase the yields of citric acid (or its breakdown products) in the presence of oxaloacetic acid, are incompatible with the above schemes. In both tissues the removal of acetoacetic acid is much accelerated by oxaloacetic acid (or its precursors). The effect is greater under anaerobic than under aerobic conditions. A detailed examination of the products of the anaerobic interaction between acetoacetic and oxaloacetic acids—involving the quantitative determination of acetoacetic, oxaloacetic, β-hydroxybutyric, citric, *iso*citric, *cis*-aconitic, α-ketoglutaric, α-hydroxyglutyric, succinic, fumaric, malic, pyruvic and lactic acids—showed that the extra acetoacetic acid removed by interaction with oxaloacetic acid can be quantitatively recovered as β-hydroxybutyric acid.

The formation of β-hydroxybutyric acid is not due to a direct interaction between acetoacetic and oxaloacetic acids. Two substances arising in tissues from oxaloacetic acid—malic acid and α-ketoglutaric acid—were found to react with acetoacetic acid. The two reactions are:

(1) 

and

(2) 

Reaction (2) has already been observed in other tissues by Krebs and Johnson[3] (1937).

Oxaloacetic acid, when added anaerobically to tissues, is in part reduced to malic acid[4]. The portion undergoing reduction varies, according to conditions, between 25 and 70 per cent. The remaining fraction enters oxidative conditions, the chief products of oxidation being, apart from carbon dioxide, citric acid (together with *iso*citric acid, *cis*-aconitic acid) and α-ketoglutaric acid. For example[4]:

(3) 3 oxaloacetic acid → malic acid + tricarboxylic acid* + $2CO_2$

or

(4) 4 oxaloacetic acid → 2 malic acid + α-ketoglutaric acid + $3CO_2$.

When reaction (1) is superimposed on (3) or (4) oxaloacetic acid is regenerated from malic acid and the reformed oxaloacetic acid will react again according to (3) or (4). The overall effect of (1) and (3) is

(5) 2 oxaloacetic acid + acetoacetic acid → tricarboxylic acid + $2CO_2$ + β-hydroxybutyric acid;

and of (1) and (4)

(6) 2 oxaloacetic acid + 2 acetoacetic acid → α-ketoglutaric acid + $3CO_2$ + 2 β-hydroxybutyric acid.

If (2) is superimposed on (6) the overall effect is

(7) 2 oxaloacetic acid + 3 acetoacetic acid + $H_2O$ → succinic acid + $4CO_2$ + 3 β-hydroxybutyric acid.

In our experiments the increased yields of citric, α-ketoglutaric and succinic acids were fully accounted for by the above schemes.

A study of the reactions of acetoacetic acid in the

* 'Tricarboxylic acid' stands for the mixture of citric, *iso*citric and *cis*-aconitic acids, 'malic acid' for the mixture of malic and fumaric acids.

presence of oxygen does not indicate that there are other reactions between oxaloacetic and acetoacetic acids besides (1) and (2) in sheep heart muscle. Under the conditions of our experiments oxaloacetic acid had no effect on the *oxidative* breakdown of acetoacetic acid. The intermediate stages of this process must still be regarded as obscure.

Experimental details are to be published in the *Biochemical Journal*.

## Substitution of Whole Stomach Extract for Vitamins in the Treatment of Malignant Infantile Pellagra

DURING the last three years, close on three hundred children suffering from acute malnutrition have been admitted to the non-European Hospital, Johannesburg. More than 60 per cent of these infants manifested the clinical signs of infantile pellagra. The dominating features of this disease were œdema affecting upper and lower extremities, and in severe cases the face, eyelids and genitalia; this œdema was associated with pellagrous skin lesions on the legs, buttocks, back, arms and face, grey hair or alopecia, as well as patchy or diffuse dermal depigmentation. The stools were, as a rule, bulky, pale and foul-smelling, and contained much unsplit fat. The serum proteins, both albumen and globulin, were extremely low, a mild microcytic anæmia was common, and the liver, on biopsy and at post-mortem, was diffusely fatty. This severe form of malnutrition is apparently identical with that described by other investigators[1,2,3,4].

Trowell[5], an outstanding worker in this field, has repeatedly recorded the unresponsiveness of this disease to vitamin therapy, including nicotinic acid, and recorded a 90 per cent death-rate. For this reason he decided to discard the name 'infantile pellagra', and to call it 'malignant malnutrition'.

In our experience, not only has vitamin therapy failed to save the lives of more than 50 per cent of these children, but also in many instances we strongly suspected that vitamin therapy aggravated the disease and even hastened death. This opinion is substantiated by the sudden increase in œdema, as well as of fatty change in the liver, when vitamins were administered. Blood and serum transfusions also proved valueless. In these circumstances it was essential to seek some other method of saving the lives of these children.

We established, by an improved liver biopsy procedure, that the microscopic appearance of the liver is a most valuable method of assessing the severity of the condition and is certainly more reliable than the clinical picture or any of the laboratory findings. We therefore adopted the liver biopsy method as a routine procedure in gauging the condition of the child on admission and the effectiveness of our therapy. Twenty children were studied by this method. Of these, seven were treated with thiamin, nicotinic acid or brewers' yeast administered either orally or parenterally; seven were given 5 c.c. of Abbott's crude liver extract intramuscularly twice daily for seven days, and the final group of six cases were treated with 10 gm. of ventriculin (Parke Davis) plus 10 c.c. of $N/10$ hydrochloric acid daily, in one dose, for five days.

All these cases had extremely fatty livers which, from our previous observations, indicated a very poor prognosis. Progress was assessed by the clinical condition, the weight curves (as an index of the gain or loss of œdema fluid) and weekly liver biopsies.

Only one child of the seven treated with vitamins survived. The œdema increased progressively, the fat in the liver became more extensive, the children became more apathetic and died within two weeks. Five of the seven children treated with liver extract lived. The recovery was slow, the œdema subsiding gradually. Even after four weeks the liver still contained appreciable amounts of fat.

The response to ventriculin therapy was most dramatic, since all the children survived, despite the fact that clinically and by liver biopsy they were as bad as the cases in the other two groups. A loss of œdema fluid shown by the decrease of 1–1½ lb. in weight was usually observed within twenty-four hours. Moreover, the clinical condition improved in a remarkable fashion, and the liver was almost free of fat within two weeks.

Whole extracts of hog's stomach has occasionally been used for the treatment of pellagra in adults with good results[6,7,8]. In seven cases of severe pellagra in adults we have found that, except for the mental symptoms, which respond slowly, ventriculin is a much more rapid and effective treatment than nicotinic acid or other vitamins.

Owing to restriction of facilities, it has not been possible to conduct a more extensive investigation of the value of ventriculin in treating severe malnutrition in children. However, even with this limited material we feel justified in concluding that: (1) Stomach extract is a life-saving drug in severe infantile pellagra and should be given universal trial. (2) Stomach extract can be regarded as a lipotrope in view of the rapidity with which it depletes the fat from the liver in infantile and adult pellagra. (3) Biopsies reveal extensive liver damage in adult and infantile pellagra. (4) In view of the fact tha both adult and infantile pellagra respond to a single form of therapy, there is no justification for regarding them as different diseases.

We wish to acknowledge our indebtedness to Dr. Selby for allowing us access to the children under his care.

## A Rapid Method of Estimating Moisture in Dehydrated Fish

THE determination of moisture in foods by extraction with alcohol has been limited by the lack of a rapid and accurate method of estimation of the resulting alcohol–water mixtures. Robertson[1] has recently shown that both dicyclohexyl and a mixture of seven volumes of 'Elaine' kerosene and one volume of Standard White Oil No. 7 (both products of the Standard Oil Co. of California) possess very critical temperatures of solution with water–alcohol mixtures. The critical temperature of solution is clearly demarcated by loss or appearance of turbidity with the paraffin mixture, but this is preceded by a hazy appearance with dicyclohexyl. As the method can be adjusted to give a range of up to 20° C. for a water content of 1 per cent in water–alcohol mixtures, the method appeared to be sufficiently critical for food analyses.

As neither dicyclohexyl nor the grades of paraffin mentioned by Robertson was available, a blend of Standard White Oils No. 5, No. 12, and liquid paraffin was used. This blend approximated to the physical characteristics of Standard White Oil No. 7. The critical temperature of solution was determined for water–alcohol mixtures of known low water content with (*a*) 7 parts of kerosene to 1 part of blended white oil, (*b*) 3 parts of kerosene to 1 part of blended white oil. The ratio of alcohol–water to paraffin mixture was kept constant at 2–4. The relationships so derived were used as reference curves for all subsequent determinations. These curves are not reproduced, as each particular mixture of paraffin has a different critical temperature of solution for the same amount of water.

The time required for extraction of water from any food by refluxing with absolute alcohol or with alcohol of low but known water content varies with the nature of the food. Extraction of water from 10 gm. dehydrated fish with 50 ml. of boiling alcohol reached equilibrium in 30 minutes. Only slightly less water was extracted in 15 minutes. The results obtained by the critical temperature of solution method and the more conventional methods of oven drying are compared in the accompanying table. The vacuum oven used was designed and constructed by workers at this Laboratory and gives quicker drying than the normal laboratory design.

WATER CONTENT OF DEHYDRATED FISH DETERMINED BY DIFFERENT METHODS.

| Sample No. | Per cent loss in weight | | |
|---|---|---|---|
| | Crit. temp. of sol. method | Vacuum oven 20 hr. at 70° C. | Oven drying at 100° C. |
| 1 | 9·5 | — | 9·2 (6)* |
| 2 | 5·7 | 5·8 | 6·0 (6½) |
| 3 | 7·7 | — | 8·1 (9) |
| 4 | 7·8 | — | 7·5 (7) |
| 5 | 8·55 | 8·1 | 8·5 (6) |
| 6 | 9·5 | 9·4 | 9·25 (6) |

* Hours of drying to give constant weight.

The results obtained by the three methods do not differ by more than 0·4 per cent except for sample 5, where there is a maximum difference of 0·45 per cent between the results obtained by vacuum oven drying and the critical temperature of solution method.

The samples determined were of four common South African fish of commercial importance with oil contents on a fresh-weight basis ranging from about 0·1 to 3·0 per cent.

The critical temperature of solution method can be recommended for rapid and accurate determination of the water content of dehydrated fish, since with this material there is rapid and complete extraction of water by alcohol and the necessary calibration curves need only be drawn up once for a single large consignment of kerosene and white oil. Where dicyclohexyl is obtainable, even this is not necessary, since the curve is given by Robertson[1]. It is necessary to take precautions to dry all glassware thoroughly.

Work is proceeding with other dehydrated products, including vegetables, but these latter present certain difficulties.

## Measurement of Potential Difference as a Method for Studying the Action of Water on Lead Pipes

WHEN working a R.A.M.C. mobile hygiene laboratory in Northern Ireland in 1941, I found that a number of the water samples submitted for examination had a definite plumbo-solvent action. Thresh[1] showed that mere acidity or alkalinity was of minor importance, but the presence of lime with a silicate or organic acid, such as citric, lessened the action.

Nine samples attacked lead; they were mostly acid and very soft. The customary routine was followed, freshly scraped and old lead surfaces being immersed and the effects noted. Such comparative tests can give an approximately quantitative determination of the rate of attack. Thus water from the Glen River, Newcastle, was at *p*H 5·8 and gave a strong reaction for lead after 20 minutes with a fresh surface. The source, recognized as dangerous, is regularly treated with sodium silicate. The water was then at *p*H 8 and gave only a slight positive test for lead after an hour; the new surface tarnished rapidly. Water from Castlewellan Lake, at *p*H 7·3 and with ten parts per million temporary hardness and thirty permanent, gave a negative result after twenty minutes and showed less lead after one day than did the untreated river water after twenty minutes.

The diverse chemical factors affecting the action of water on lead appear to be summed up by a measurement of the difference of electrical potential between old and new lead surfaces immersed in the sample. Differences of a few millivolts were, however, found between various old surfaces. Accordingly, the gold electrode, supplied with the potentiometer provided in the mobile hygiene laboratory for *p*H determinations, was used in measuring the potential difference between gold and old or new lead surfaces.

| Period of immersion | | Two min. | | Ten-forty min. | | About one day | |
|---|---|---|---|---|---|---|---|
| Sample | *p*H | Old | New | Old | New | Old | New |
| Distilled | 6·0 | 617 | 725* | — | — | — | — |
| River | 5·8 | 584 | 682 | 537 | 581 | 472 | 476–505† |
| River, with silicate | 8·0 | 507 | 506 | — | — | — | — |
| Lake | 7·3 | 514 | 556 | 390 | 396 | 282 | 390 |

* Obtained indirectly, 108 millivolts more than old surface.
† After stirring.

A few results are shown in the table, but pressure of routine work rendered it impossible to follow the changes at precisely regular intervals; the units are millivolts between gold and lead surfaces at about 12° C.

The treatment of the town supply with silicate is obviously very effective as the new surface is rapidly inactivated. Since the continuation of the work has had to be postponed, this outline of what appears to be a useful method is now presented; it is not mentioned in the 1942 edition of Thresh, Beale and Suckling's book "The Examination of Waters and Water Supplies".

## Active Nitrogen and $N_2^+$ ($X'$) Ions

IN a recent paper[1] I put forward the hypothesis that active nitrogen is simply the positive ions of the nitrogen molecule, $N_2^+$ ($X'$) produced in the discharge tube. It was suggested that the excitation of the First Positive Bands—the characteristic active nitrogen spectrum—is due to the neutralization of $N_2^+$ by a three-body collision, with the neutral $N_2$ molecule as the third body, in the volume rather than on the surface of the discharge vessel. Thus, $N_2^+ (X') + e + N_2 \rightarrow N_2$ ($B$ state) $+ N_2$ ($A$ state). The energy relation is satisfied if the $N_2^+$ molecule, on neutralization, drops to a vibration level in the neighbourhood of $v' = 10$ of $B^3\Pi$ state (9·26 eV.). and the neutral $N_2$ molecule is raised to the $A^3\Sigma$ state (6·14 eV.). It is now pointed out that the transition of $N_2^+$ ($X'$) to $B^3\Pi$ ($v' \simeq 10$) on neutralization satisfies the Frank-Condon principle, namely, that the change in the nuclear distance (near turning point) is very small.

The remarkably long life of active nitrogen was attributed to the fact that the conditioning or special treatment of the walls of the discharge tube which is so essential for long life prevents recombination of the ions and the electrons taking place on the walls. The recombination thus being confined to the volume proceeds slowly by a three-body collision process, giving long life to the afterglow. In the present communication, certain properties of active nitrogen connected with the presence of ionization in the afterglow will be discussed, and it will be shown that they receive simple and satisfactory explanation on the above hypothesis.

The subject of ionization in active nitrogen has been studied by Constantinides[2] and in great detail by Lord Rayleigh[3]. Two of the experimental results of Rayleigh which have an important bearing on the present hypothesis are as follows:

(1) The ion density as computed from observation of ionization current flowing between two electrodes is *less* than the number of photons emitted per unit volume from the glowing gas (in the initial stage).

(2) Introduction of neutral $N_2$ increases the ionization current and also the intensity of afterglow.

These experiments require careful consideration as otherwise they can easily be interpreted as invalidating the proposed hypothesis. For example, according to the proposed hypothesis, the density of ions cannot be less than the number of photons emitted per unit volume. It will be shown, however, that the hypothesis not only offers a simple explanation of these apparently anomalous results but, in fact, is confirmed by them.

For explanation of (1) we recall that according to the hypothesis, the conditioning or treatment of the wall prevents the neutralization of electrons and positive ions on the glass surface. This, in other words, means that by some process—we do not as yet know how—the conditioned or treated wall prevents the electrons and positive ions from coming into contact with the surface. According to the hypothesis, therefore, ionization current between two electrodes (the surfaces of which, as in the experiment under consideration, are treated) will be extremely small compared to that which would otherwise be obtained if the electrode surfaces are normal and unconditioned. The ion density computed from currents carried by such electrodes would therefore be much smaller than the true ion density. It should be noted that even untreated metallic electrodes would not, as may at first sight be expected, yield better results. This is because such electrodes when immersed in active nitrogen become conditioned, as is evinced by the fact that they do not permit recombination on their surfaces. Perhaps metallic electrodes which can be warmed to 'poison' their surfaces would, if used, indicate the true ionization current.

These latter conclusions are based on another experiment by Lord Rayleigh[4]. It is found that a small piece of metal held in active nitrogen is ordinarily dark and is unaffected. If, however, it is warmed, or is not far from the direct discharge, it starts glowing presumably because active nitrogen begins to deliver energy to it. The obvious explanation of this experiment, on the basis of the present hypothesis, is that ordinarily no reaction takes place on the metal surface, because the metal immersed in active nitrogen becomes conditioned and prevents the access of ions and electrons to it. But if the conditioning is destroyed by any means (by warming or by putting the metal close to the discharge) then reaction on the surface starts and the released energy (15·58 eV. per electron and ion recombined) raises its temperature to a glow heat.

Increase of afterglow in experiment (2) is explained by the increase in the density of $N_2$, which causes an increase in the value of the recombination coefficient. The increase in the ionization current can be explained if it is assumed that the introduction of neutral $N_2$ from outside temporarily 'poisons' the electrode surfaces so that ions and electrons flow to them with less obstruction.

No other hypothesis so far put forward gives any explanation of the occurrence of ions in active nitrogen, or of the fact that the afterglow and the ionization in it are not wholly independent.

Closer examination shows that the hypothesis gives similar simple explanations of various other phenomena observed in active nitrogen even to small details. These and the explanations of the phenomena mentioned above are being examined by Mr. J. S. Chatterjee (Ghose Research Scholar in physics). Mr. Chatterjee is also arranging certain crucial experimental tests for the hypothesis. These will form the subject matter of a future communication.

If the proposed hypothesis of active nitrogen be correct, then the proper subject of investigation now would be the study of the change which the conditioning or the treatment produces in the walls of the

discharge vessel and which prevents the surface recombination of $N_2^+$ ions and electrons.

## Derivation of Maxwellian Relaxation Times from Tensile Data

MAXWELL'S[1] relaxation time ($t_r$) is defined as the ratio of viscosity ($\eta$) to shear modulus ($n$), and is derived from the expression $-\delta(\log S)/\delta t$, of which it is the reciprocal ($S$ is the shear stress dissipating at constant strain).

It is well known that for fluids $\eta = \tau/3$, where $\tau$ is the "coefficient of viscous traction" (Trouton[2]), and for elastic solids, that $n = E/2\ (1 + \Pi)$, where $E$ is Young's modulus and $\Pi$ is Poisson's ratio, which is $\frac{1}{2}$ for fluids. But it is often overlooked that the latter expression is only applicable to small strains; there is also the question of isotropy, which will not be discussed here. Further, the validity of the former to flow conditions depends on the special nature of liquids (see especially Love[3]).

Now that the theory of elasticity is being increasingly applied to 'high-elastic' materials for which so-called 'moderate strains' may be of the order of several hundred per cent, it is important that the limitation of the $2(1 + \Pi)$ expression should be more widely realized. A number of authors (Schofield and Scott Blair[4], Kuhn[5], Bennewitz and Rötgers[6], Taylor[7], Robinson, Ruggy and Slantz[8], etc.) have derived relaxation times from tensile data for large strains using the $2(1 + \Pi)$ expression. In some cases it is quite clear that it is only the order of magnitude of $t_r$ that is significant: in others the limitations of the treatment are not made clear. The applicability of the expression does not depend only, as Simha[9] appears to suggest, on the constancy of $\Pi$ or on the validity of Hooke's Law: in fact, the meaning of this latter criterion is liable to ambiguity where large strains are concerned. The essential point is that the original calculation of $2(1 + \Pi)$ depends fundamentally on the deformations being small.

Fluid behaviour is defined in such a way that large strains must be expressed by the 'natural' formula

$$\int_{l}^{l_0} \frac{dl}{l} = \log_e l_0/l$$

(for a length increase from $l_0$ to $l$) and such strains are additive. The usual 'engineering' formula, $l - l_0/l_0$, is not additive for large strains and the 'extension ratio', $l/l_0$, which is much used in the theory of rubber structure (see Wall[10], Treloar[11], etc.), is multiplicative, being numerically equal to the antilogarithm of the 'natural' strain. Some authors, such as Latshaw[12], do not appear to be clear about this. The extension ratio has the advantage that it relates tensile to shear strains by a simple expression irrespective of strain magnitude[3].

Modern 'high-elasticity' theory is based largely on the work of Kuhn[5] and that of Alexandrof and Lazurkin[13], Lazurkin[14] and Gurevich and Kobeko[15]. This latter school is concerned with what are called by the authors 'relaxation times' but, being quite different from those of Maxwell, are now generally known as 'orientation times'.

The orientation time is the time required for a strain to reach $1 - 1/e$ of its equilibrium value under constant stress. Although said to apply only to super-cooled liquids, the materials concerned do not have that property of liquids which justifies the use of the classical expression relating tensile to shear conditions, since there is no unique rate of shear for any given stress. It is not clear whether orientation times refer to shear or to tensile-compressive strains. Alexandrof did compression tests whereas Gurevich and Kobeko used shearing conditions. The discrepancy does not appear to have been noted.

In fitting equations such as that of Nutting[16] which do not involve entities like viscosity and relaxation time, the empirical use of $2(1 + \Pi)$ is justifiable; but this is scarcely the case in deriving values of $\eta$ and $t_r$, unless it be made quite clear that the treatment may be only very approximate for large strains. For materials of high consistency, a relaxation time defined in terms of the dissipation of tensile stress and a coefficient of viscous traction would really be preferable to the more usual $t_r$ and $\eta$.

I have been helped in the unravelling of this very confusing situation by so many friends that individual acknowledgment is impossible.

## Smoke and Rain

IN a paper published in 1929[1] the conclusion was drawn from observations made in two or three different ways that smoke discharged into the atmosphere tends to promote rainfall and to precipitate rain in highly moist air when, without smoke, it would not have fallen. One test was to compute the rainfall on each day of the week, and the result showed that on an average of thirty years, Sundays had rather less rain than weekdays by about 6 per cent, or more correctly, the average of weekdays had an excess over Sundays by this amount. As factories in Rochdale and neighbouring Lancashire towns do not work on Sundays there is then a general absence of smoke in the air, although

domestic smoke, which is of less importance, continues. The outpouring of factory smoke on working weekdays was considered to be the cause of the excess of rain on weekdays over Sundays.

Since the results of thirty years rainfall were published fifteen years have passed, and the rainfall for each day of the week for this later period has again been computed and has been combined with the previous thirty years so that a total of forty-five years is now available. The following are the average annual amounts of rain in inches for each day of the week (1) for the thirty years, 1898–1928, (2) for the forty-five years, 1898–1943 :

| | Sun. | Mon. | Tues. | Wed. | Thurs. | Fri. | Sat. | Average | Total |
|---|---|---|---|---|---|---|---|---|---|
| (1) | 6·17 | 6·88 | 6·68 | 6·49 | 6·65 | 6·27 | 6·63 | 6·54 | 45·77 |
| (2) | 6·01 | 6·44 | 6·30 | 6·45 | 6·40 | 6·25 | 6·56 | 6·34 | 44·41 |

From this it is seen that the excess of rain on weekdays over Sundays, which was shown in the thirty years record, is again clearly in evidence in the longer record of forty-five years, a period long enough to make it improbable that the result is fortuitous.

It would not, however, have been surprising if the difference in rainfall between Sundays and weekdays had become less marked as time progressed, since electric power, supplied from a distant source, has in recent years replaced, to a considerable extent, steam power with its attendant pollution.

Unless there is a natural seven-day period in rainfall with its minimum occurring on Sundays, which may be ruled out, the conclusion is that the result found above is due to human agencies, and the most probable agency is smoke in the atmosphere.

## Scientific Research

IN *Nature* of May 6, I find a very interesting and very hopeful discussion of the problems of scientific research in Britain. Yet it seems to me that there are some aspects of the matter which have not been sufficiently considered.

(1) The cultural value of research. It appears to be generally assumed that the purpose of science is almost wholly that of increasing material wealth. Surely it has also another purpose, perhaps no less important, that of enabling man to understand and appreciate the world he lives in. This cultural aspect, rightly understood, justifies scientific work which may have no significance or relation to material wealth. It is here that science is connected with literature, with poetry, with the emotional life of mankind.

(2) Certainly the remuneration of scientific workers should be increased, but it is difficult to say what that remuneration is in any given case. In the universities, men are paid primarily as teachers, and do what scientific work they can, or wish. But undoubtedly they are appointed to their positions partly on account of their scientific standing, and thus are indirectly paid. It is a curious circumstance that museums expect to get scientific workers to spend months or years in the study of their collections, without any thought of payment. On the contrary, they expect the workers to show gratitude for permission to study the collections, and they do show it, fully appreciating the work which has been done, and the expense incurred, in assembling the materials.

(3) Provision must be made for adequate publication. Young men, entering upon a field of research, will not spend years on a revision or monograph which may never see the light. Not only should large and important works be published but also (as is customary) shorter papers to keep the scientific world aware of what is going on, and encourage co-operation. But still another sort of publication is needed. We need more small, well-illustrated books, written in simple language, to interest the general public in scientific work.

In all these matters, very considerable progress has been made in Great Britain, but when scientific work is under discussion they should not be overlooked.

T. D. A. COCKERELL.

University of Colorado,
Boulder, Colorado.

## Importance of Film Records

A NUMBER of amateurs are making films frequently of unique scientific interest. It may be that by patience an ornithologist has managed to secure some pictures of bird behaviour which may never be duplicated for a generation or more. It may be that a medical man has made a motion-picture record of a rare case-history or a film of a particular method of conducting an operation. It may be that an anthropologist has secured film records of fast disappearing tribal ceremonies or, in the case of our own country, a folk survival. Any worker in any field may indeed make a record which has more than a personal interest.

Most amateurs work on negative reversal stock if they are taking black and white pictures. No master negative, therefore, exists. The same is even more true of the colour films which amateurs are tending increasingly to use. The result is that each time the film is run through the projector, it depreciates slightly in quality. In the end it wears out, and people are thenceforth denied the knowledge which only this film can give.

To make a black and white negative from which prints can be taken or to make a master copy of a colour film from which other copies can be taken is relatively inexpensive ; but nevertheless it is usually beyond the individual's pocket. In any event, is there any reason why he should make a special negative or copy to meet a hypothetical demand if other people do not share his views as to the importance of the topic ?

So valuable film records are disappearing. Is there any means by which this may be prevented ? Would learned societies, for example, be willing to set up special committees to appraise the value of any films submitted to them and, if they reach the requisite standard, would they be ready to put on one side sufficient funds to make a master copy for preservation ? Can any of the big trusts be persuaded to interest themselves in making available something of the order of not more than £1,000 a year in order to set such a scheme going ? Is there any point in this Institute convening a conference to obtain expressions of opinion ?

# THE YEW TREE (*TAXUS BACCATA*)

By ALEXANDER L. HOWARD

"The warlike Yew by which more than the lance
The strong arm'd English spirits conquer'd France."
DRYDEN.

THIS romantic but rather sombre tree has for long ages been connected in simple country minds with superstitious stories of illness and death. All the old authorities on trees have lurid tales to tell of its poisonous effect on both man and beast, and it is therefore not surprising that the yew has never had a fair chance in England, but lived out its long life with little help or encouragement.

As long ago as 1662 John Evelyn wrote:

> "Since the use of bows is laid aside among us, the propagation of this tree is quite forborne. But the neglect of it is to be deplored; seeing that the barrenest grounds, and coldest of our mountains, might be profitably replenished with it."

Much has been written, and many reasons advanced for its invariable proximity to churches and graveyards. It has been suggested that this may have been partly to secure its continued cultivation on account of its value for bow-making, partly to safeguard cattle from its poisonous leaves, and partly because its rather sombre evergreen branches made of it a fitting symbol of death and immortality. The first of these cannot be accepted—the quality of the yew grown in England appears to have been inferior to that obtained from Spain, for Boulger says:

> "It was to bows of Yew that we mainly owed the victories of Crecy and Poictiers; and Edward IV enacted that every Englishman should have a bow of his own height. English Yew-wood, however, for this purpose, only fetched one-third the price of that which was imported."

Further, the greater number of, if not all, the yew trees by churches are living, nor have we any record of any being felled for bow-making. Mr. Teulon Porter also tells me that in past days the parson's revenue partly consisted of the licence to feed cattle in the churchyard, which negatives the second reason: we must accept the last as being the most probable.

Throughout the ages yew has been used as an emblem of death and burial, and this custom, which is even mentioned in ancient Greek and Roman records, has insensibly become a universal tradition, very ably expressed by Johns:

> "Generation after generation might be gathered to their fathers, the Yew tree proclaiming to those who remained that all like the evergreen unchanging Yew were yet living in another world, the life which had been the object of their desire."

"Of all the trees in England,
Oak, Elder, Elm and Thorn,
The Yew alone burns lamps of peace
For them that lie forlorn."
WALTER DE LA MARE (1873).

and

"My shroud of white, stuck all with Yew."
SHAKESPEARE.

The yew has a short irregular bole, with strong-limbed branches somewhat resembling those of the hornbeam in habit of growth. These are densely covered with a dark green cluster of needle-like leaves spreading widely with a broad crown. Some of the trees are brightened at intervals by clusters of golden or red berries, according to the variety.

It shares with the oak the claim to live the longest life of any tree grown in Great Britain, but Elwes thinks that its great age has been much exaggerated by many authors, particularly the great Swiss botanist De Candolle. Elwes refers his readers to Lowe, who proves "that the average rate of growth is about 1 foot of diameter in 60–70 years in both young and old trees". He also says that there is:

> "abundant evidence to show that though old trees grow at intervals much more rapidly than young ones, they do not grow uniformly but have periods of comparative rest, and that the increase of girth is fastest when old trees have lost their heads and the stem is covered with young shoots.
>
> No tree has such a remarkable faculty of covering up wounds or injuries by the growth of fresh wood from the outside, and even after the main stem is completely dead, fresh and entirely new stems may grow up around it and form a new tree around the dead one. For this reason most of the yews of very large size are mere shells, and even when no hollow can be seen from the outside, decay—which is often indicated by moisture running from holes in the trunk—has set in."

It is impossible in this article to enlarge upon this question of the age, about which many authorities have already written extensively, but after exhaustive inquiry into the history of a number of yew trees, and study of the growth of many that have been felled, I am inclined to the view that the ages claimed by tradition may be correct.

It is equally impossible to enumerate the many outstanding examples of yew trees which have been commented upon by all authorities since Evelyn's time, but some are specially worthy of mention. Elwes describes in his "Timbers of Great Britain and Ireland" trees at Midhurst:

> "They consist of four avenues of yew trees forming a square of about 150 yards, together with a grove of yews at the upper end which average, as nearly as I could measure them, about 75 feet in height, but some probably exceed 80. These trees are for the most part sound and healthy, though little care has been taken of them, and some have fallen. They are remarkable not only for their great height, which exceeds that of any other yews on record in Europe, but on account of their freedom from large branches, many having clean boles of 20–30 feet, with a girth of 8–9 feet."

Mr. Thomas Roberts of Cowdray informs me that these avenues are in good healthy condition to-day (1944). Elwes also refers "to the largest pure yew-wood in England on the downs three miles west of Downton, Wilts, on the property of the Earl of Radnor" partially planted, and adds an account of "The Little Yews"—another wood near by, which contains much finer trees. He says:

> "the Cherkley Court Yew Wood is the best in England. . . . The wood covers an area of 50 to 60 acres in a shallow valley forming part of the old Ashurst estate, about three miles from Leatherhead in Surrey, on the east side of the old pilgrims' road to Canterbury."

Another is at Castle Eden Dene in Durham.

With the knowledge we have of these outstanding plantations, which date from very early times, we conclude that there must have been a far greater interest in its cultivation than that which has obtained for the last three hundred years or even more. This view is supported by the fact that it amounted to almost a penal crime to make use of any yew wood

other than for bows prior to the year 1550. It is likely, therefore, that the demand was so great that the better quality was becoming scarce, and even at that early date it was found necessary to import supplies from Spain.

It appears also that at a very early date it became fashionable to plant yew walks. One such walk still flourishes to-day at Huntington Castle, Clonegal, Ireland, and regarding this Mr. Manning Robertson writes to me under date of June 27, 1944, as follows:

"This consists of 122 trees in a row: the row is some 360 feet long and there are 'return ends' making three sides of a rectangle. The largest tree is 41 feet high and 12 feet 9 inches girth at 5 feet from the ground. Many of the trees have interlaced and grown together—like Banyan trees. Little is known of the Walk's history, but it is almost certainly monastic, and tradition has given the age as 600 years: it is still in perfect condition."

Elwes mentions:

"a remarkably fine yew walk at Hatherop Castle, Gloucestershire . . . which is supposed to be about 300 years old, in which the trees average about 60 feet in height with a girth of 9 to 12 feet."

The importance of the yew as hedgerow has been recognized for many centuries. Its use for the partition of fields has been debarred because of the danger to animals. Although it is slow in growing to perfection, as protection for property it has been for long ages justly prized, and is not only very decorative but also presents a formidable barrier, impossible to climb and very difficult to destroy.

John Evelyn evidently felt strongly on the question of yew hedges, as he wrote:

"the Yew tree has been generally cultivated for the pleasure garden, to be clipped into the shape of beasts, birds, etc., or for hedges. Whoever is pleased with such figures can raise no tree more proper for the purpose, as the branches and the leaves may be clipped and fashioned into almost any form or shape. But as this method is justly exploded, and as everyone who has the least pretension to taste, must always prefer a tree in its natural growth to those monstrous figures, the Yew is now chiefly planted for wilderness quarters, and for hedges, for which service it is excellently well adapted."

With regard to its uses for timber, and quoting from "The Timbers of the World":

"This useful and highly decorative wood is now little known or esteemed, although it presents qualities which deserve much better recognition. If the economic use of domestic woods were practised in this country as it has been in France and Germany, yew would have undoubtedly been brought into prominence. The colour is pale red, somewhat like cherry wood or pencil cedar: it has a beautiful smooth lustrous grain. Sometimes it is handsomely figured, and occasionally has a burr growth, the produce of which will compare favourably with amboyna, and has indeed actually been mistaken for it. The strength and elasticity of yew-wood has been known for centuries, particularly on account of its use for bows. . . . At Sir Mark Collet's house, near Sevenoaks, some handsome doors are made of yew. The stiles and rails are of the ordinary figured wood, and the panels of exceptionally fine figured burr. The colour has deepened with long exposure, assisted by careful polishing, and is now a rich red brown. Yew is particularly suited for chair-making, and some very fine specimens of considerable antiquity are to be found in many places. Elwes alludes to an extremely handsome arm-chair in Hornby Castle, the property of the Duke of Leeds. The date is about 1550. It is made of Yew, which adds to its rarity, for up to this time it was practically penal to employ yew-wood for any other purpose than the manufacture of the national weapon; in this instance the wood has become close, as hard as steel, and of a beautiful dark amber colour. The wood, though it is difficult to obtain, is also valued for brush-backs."

Yew is specially liable to the growth of 'burrs', which I have already mentioned. About thirty years ago an outstanding example was sent to me from the Caucasus, measuring more than seven feet in length, more than four feet in depth, and weighing nearly a ton. Purchased by an American, it was cut into veneer, yielding some of the finest specimens of yew burr ever seen.

It is difficult to decide whether this unique tree should be extensively cultivated; but it is certain that as a tree it has many interesting and unusual qualities, and as timber it is a fine medium for decorative work of all kinds.

## THE UNIVERSITIES AND INDUSTRY

THE "Report on the Extension of Scientific Research in Manchester University, particularly in Relation to the Industries of its Area" (Manchester University Press, 1944, 1*s*.) which has been prepared by a committee of professors and industrialists, all of whom are members of the governing bodies of the University, to assist the University to make a considered estimate of the increase in income necessary to ensure that its science departments may undertake their proper responsibilities in the nation's economy, is of much more than local interest. In the first place, it amplifies some passages in the recent pamphlet of Sir Ernest Simon on the development of British universities, while at the same time it offers some measure of the value of the Joint Standing Council of members of the University of Manchester and the Manchester Chamber of Commerce which has been under discussion between the two bodies, as announced by Mr. A. H. S. Hinchliffe at the last of the series of meetings on "Science and Industry" arranged by the Chamber. Again, in its chapter on research and teaching, it puts concisely much of the argument advanced in the recent House of Commons debate, by the Parliamentary and Scientific Committee and elsewhere, and attempts to give concrete expression to the means by which those arguments may be given effect.

The statement includes detailed reports from the Chemistry and the Electro-Technics Departments, which have been chosen because of their relevance to some of the more important scientific industries of the area. The first of these reports comes from Dr. C. J. T. Cronshaw, Prof. A. R. Todd and Prof. M. Polanyi; and the second is by Dr. A. P. M. Fleming and Prof. Willis Jackson. The broad conclusion reached is that the effective discharge of the functions of the science departments of the University of Manchester in the post-war period involves doubling the expenditure of the Departments as a whole. Even this would provide for no new developments outside existing departments, and the report proposes an increase of about 50 per cent in the first year, rising to 100 per cent in the fifth year after the War.

In its introductory survey of research and teaching, the statement emphasizes that the primary duty of the science departments must be research at the highest levels of which they are capable. The first step towards improving teaching standards in any

scientific department must be to increase the facilities for, and the volume and pace of, research. The expansion of research facilities in the science departments is thus placed first in order of importance; it comes before the expansion of student numbers, because the standard of a university depends on it.

Deprecating the distinction between 'pure' and 'applied' research, the statement prefers to speak of 'academic' and 'industrial' research, distinguishing the different modifying and conditioning factors which surround the same intellectual process. The outlook, approach and method of the research worker are the same whether he is in a university or in industry. Development work, which is the conversion of results of research into processes of economic production, depends for its success on men in industry who combine scientific knowledge with experience of practical problems in their particular field. The statement suggests that the flow into industry of men who have graduated in a strong science department, who have learned as postgraduates an outline of research technique, and who keep in touch with the work of academic laboratories, will reduce very materially the time-lag between research and development. The real and permanent link between university science departments and industry is in research.

Pursuing this argument, the chapter on post-war development in chemistry, from its review of the development of chemical industry in Germany, argues that a first-class scientific industry cannot be built up in the absence of first-class universities which are teaching science; while, on the other hand, such universities cannot long continue to function in the absence of an industry capable of exploiting scientific developments and willing to employ scientific staffs trained in them. The organic chemical industry in the past has been built up on coal and can continue to be based on coal in spite of the threat of the natural oil fields seeking new outlets for their new materials; and the statement urges that without an intensive research effort, both by industry and by the universities, comparable with that taking place in the United States, the organic chemical industry in Great Britain will falter and a great natural asset, coal, will be playing a lesser part in world development than is its due share. Besides the plans for an increased flow from the university of research chemists—representing in detail a department with an annual intake of fifty honours students and a total of some eighty research workers (including staff)—a flow from industry is recommended, such as the practice of releasing senior men in industry to pursue research in academic schools, for say two-year periods, and facilities for academic workers to visit other centres abroad for limited periods.

The following report, on post-war developments in electro-technics, similarly urges that what is particularly needed by the engineering schools is a scheme for the return, for limited periods, of selected men from industry. In the period between the two wars Great Britain lagged behind other industrial countries in the production for world consumption of those engineering goods and tools of production which result from the application of recent scientific and technical research and invention. This was a direct consequence of our inadequate research activity in the branches of science concerned, and in electrical engineering the effect was particularly marked on the telecommunications side. If, however, those university physicists and engineers who, either in their university departments or elsewhere, have contributed so much to the war-effort, are given comparable research facilities in the post-war period, the intimate liaison between university scientific workers and their industrial colleagues which has been established will develop to the great benefit of both the universities and industry, and of the country as a whole. Collaboration between the engineering schools and industry is particularly desirable in the attack on the border-line subjects between pure science and engineering, especially in the study of the properties of materials in relation to their chemical composition and physical structure.

With regard to the Manchester Department of Electro-technics, an increase in the number of undergraduate students to an average of twenty to twenty-five a year is suggested, and accommodation for up to ten men in each of two postgraduate courses. Even if some of the postgraduate teaching is conducted by part-time specialist lecturers from the local industry, the scheme will involve doubling the present full-time staff, with a further supplement to the laboratory staff. On a rough estimate, a further £20,000, based on pre-war costs, spread over the five-year period, will be required to bring the laboratories into a condition to initiate the scheme.

The statement does not touch on the question of a School of Chemical Engineering in Manchester raised by Sir Ernest Simon in his pamphlet. The spirit and trend of the statement, however, suggest that the Joint Standing Council at present under consideration may not only stimulate further the contact between the University of Manchester and the industries of the north-west of England, but also facilitate inter-regional consultation with regard to the founding of new schools where they will best serve national needs and not merely local interests or prestige.

## DEVELOPMENT OF THE CARIBBEAN REGION

THE report of the West Indian Conference held at Barbados during March 21–30, 1944 (Colonial No. 187. H.M. Stationery Office, 1944. 6*d*. net), contains accounts of the findings of the six committees which considered the agenda of the Conference. One of these specifically considered the Caribbean Research Council and possibilities for its expansion. In addition to the existing Sectional Committee on Agriculture, Nutrition, Fisheries and Forestry, the establishment of four further sectional committees is recommended, for public health and medicine, for industries, for building and engineering research, and for social sciences. Creation of a statistical unit to serve all sectional committees is recommended; and also early consideration by the Research Council of legal and fiscal problems related to collaboration among the research institutions of the Caribbean, with the view of submitting proposals to the Anglo-American Caribbean Commission for possible consultation with the Governments concerned.

Three general points are emphasized by the committee considering the Caribbean Research Council. First is the importance of freedom of action and independence of thought for the Research Council and its technical experts in the sectional committees, within the terms of reference specified by the Anglo-American Caribbean Commission. The Research

Council should also provide that the programmes of work of the several sections are properly co-ordinated, and that the projected investigations of Caribbean problems are approached with the view of yielding early results. Secondly, the activities of the Caribbean Research Council and the implementation of its findings depend ultimately on an enlightened public opinion among the Caribbean peoples themselves, and therefore on an improvement of their educational standards. Thirdly, the Research Council should give due consideration to the related work of institutions outside the Caribbean area and to such international agencies as may be created in pursuance of proposals made by the Hot Springs Conference on Food and Agriculture.

The extent to which opinion in the Caribbean is becoming aware of the research needs of the area may be seen in a number of proposals made by delegates in the reports of the committees dealing with other items on the agenda of the Conference. The committees concerned with means for raising the nutritional level both included such proposals in their reports. That dealing with increased local food production urged that research in the development and adaptation of foods of high nutritional and protective value and in cognate matters should be intensified through the medium of the Caribbean Research Council, and the necessary personnel provided to undertake extended programmes of research. That concerned with expansion of fisheries, after endorsing the findings of the Fishery Committee of the Anglo-American Caribbean Commission meeting at St. Thomas last August, urges that its recommendations should be implemented without delay. The Fishery Experimental Station at Mayaguez, Puerto Rico, should be a centre for technological research and a bureau for the collection and dissemination of statistics and information as well as undertaking fundamental and biological research. The most pressing lines of research are, in technology, on the capture of fish and on its handling and preservation; in biology, biological research which is necessary for the intelligent development and conservation of the fisheries, including studies on dominant species of fish, fish histories, productivity and depletion, migrations, seasonal schooling and spawning, and environmental studies on contrasted types of fishing grounds. Besides research in oceanography, such as an ecological study of the environments in which fish live, long-term fundamental research will be necessary to provide background information for the intelligent management and development of the fisheries, and as an informed basis for measures of conservation. The establishment of a fishery research institute in the British West Indies will be necessary, and such a scheme should be co-ordinated with any plans for the establishment of a University of the West Indies, or it should be affiliated to the Imperial College of Tropical Agriculture. Fishery research institutes and experimental stations should frame their research policy in accordance with the practical needs of the industry and co-ordinate their programmes on a regional basis.

This sectional report also recommends that an exploratory fishery survey in the Bahamas and Caicos, investigations on fish handling and preservation and net preservation, under local conditions, and on the commercial possibilities of sharks, crawfish, conchs, turtle and shrimp should be undertaken without delay; and that the attention of the Caribbean Research Council should be directed to the necessity for collecting and disseminating information on the commercial possibilities of sharks, the crawfish industry in the Bahamas, fresh and brackish water fish-culture and on sport fishing.

The report of the committee which considered the planning of public works for the improvement of agriculture, education, housing and public health includes a recommendation for the establishment of a Caribbean Planning Commission as part of the Anglo-American Caribbean Commission. It also recommends the institution for research on standardization of building units in various materials and the possibility of prefabricating such units in the Caribbean area, including the scientific pretreatment of lumber and standardized timber units against termite and rot at depots in each territory or group of islands.

The committee which considered industrial development recommends that the Government should help to create and to foster new industries and the development of existing industries which could survive without continued State assistance, either by undertaking research itself or by supporting approved investigations, the results of which should be made available at once to the whole area. Such research might include the erection of pilot plants at the public expense.

These and other recommendations of the sectional committees were adopted by the Conference, which further recommended that another session should be held within twelve months, and that the Anglo-American Caribbean Commission should consider the establishment of a permanent secretariat to handle the work of the Conference. Besides the emphasis thus laid on research, however, the Conference is of more than local interest as an example of Colonial regionalism in which an effective expression is given to the democratic spirit.

# POSSIBLE RELATION OF LINOLENIC ACID TO THE LONGEVITY AND GERMINATION OF PINE SEED

By DR. N. T. MIROV
U.S. Forest Service

SEEDS of some pines, such as Jeffrey pine (*Pinus jeffreyi*), can be stored in air-tight jars at room temperature for a long time. Even after ten years of storage one may expect as much as 40 per cent of viable seed. When the seeds of Jeffrey pine are sown in a greenhouse they germinate rapidly and abundantly. Many other pines, as, for example, sugar pine (*Pinus lambertiana*), have short-lived seed. Under ordinary storage conditions sugar pine seeds lose their viability rapidly, and after five years of storage their germination is usually nil. At 5° C. the viability of sugar pine seed is maintained for a long time; in one case, after eight years of cold storage, germination amounted to 86 per cent of the original. Normally seeds of sugar pine sown in a greenhouse either fail to germinate completely or give a very small percentage of germination. When, however, the seeds are chilled in some moist medium for three months at 5° C., they germinate as well as those of Jeffrey pine. This prolonged period at a low temperature, necessary for germination of refractory seeds, can be designated as the period of incipient germination.

Food storage materials of seed of the two pines are composed chiefly of fatty oil (55·5 per cent in sugar pine seed and 50 per cent in Jeffrey pine seed), proteins and sugars. It is seen that more than one half of the reserve food material in seeds of both pines consists of oil, and that sugar pine has more of it than Jeffrey pine. Analyses have shown that the oil of sugar pine seed has an iodine value of 150·5 while the oil of Jeffrey pine seed has an iodine value of 136·4. There is thus a higher degree of unsaturation in the seed oil of sugar pine.

In ordinary storage the most unsaturated component of the pine seed oil—linolenic acid—disappears gradually in all seeds but more rapidly in sugar pine than in Jeffrey pine seed. In the seeds of both species stored at 5° C., on the contrary, no appreciable losses in linolenic acid were detected. When sugar pine seeds were chilled in moist sand for three months, only traces of linolenic acid were found at the end of that period. Prolonged storage at ordinary temperatures results in decrease of germination capacity of sugar pine seed, whereas chilling in moist sand results in an increase; yet in both cases linolenic acid disappears.

Although a possible role of unsaturated fatty acids and especially of linolenic acid in germination and longevity of oleaginous seed has received very little attention, its importance in biological oxidation has been emphasized by Meyerhof[1]. This author discussed at length Warburg's findings that "of all the unsaturated acids, linolenic acid alone with its three double linkages shows autoxidation with iron". During autoxidation the number of double bonds decreases and the reaction proceeds as follows:

$$CH_3.CH_2.CH = CH.CH_2.CH = CH.CH_2.CH = CH(CH_2)_7.COOH$$

$$\begin{array}{c} | \\ CH \\ \| \\ CH \\ | \end{array} + O_2 + H_2O = \begin{array}{c} | \\ CHOH \\ | \\ CHOH \\ | \end{array} + O = \begin{array}{c} | \\ CHO \\ | \quad | \\ CHO \\ | \end{array} + H_2O.$$

Meyerhof distinguishes between the reaction *in vitro* where it stops on the conversion of linolenic acid into slightly oxidized products, and a reaction *in vivo* where it progresses as far as formation of carbon dioxide.

In stored seed where life processes are hindered, conditions perhaps are similar to those existing *in vitro*. Slightly oxidized products are formed and these are gradually polymerized into inactive substances. The degradation of the unsaturated acids, and especially of the linolenic acid, proceeds faster in sugar pine seed than in Jeffrey pine seed. During the incipient period of germination of sugar pine seed the conditions may be similar to a reaction *in vivo*. Here disappearance of linolenic acid is probably connected with respiration and also with transformation of fats into carbohydrates.

The final results in both cases are precisely the same, namely, disappearance of linolenic acid, but the course of oxidation is quite different. In one instance it possibly causes death of the seed, while in the other it probably represents the first stage of germination connected with the utilization of stored food materials.

Of course, variations in linolenic acid contents in the seed of the two pines do not explain yet why Jeffrey pine seed germinates well under ordinary conditions and sugar pine seed does not. The experiments show that it might be connected with differences in the status of growth hormone in the seeds of the two species, but the discussion of this phase of germination is beyond the scope of this paper.

## ASSOCIATION OF UNIVERSITY PROFESSORS AND LECTURERS OF THE ALLIED COUNTRIES IN GREAT BRITAIN

### ANNUAL MEETING

THE fifth general meeting of the Association of University Professors and Lecturers of the Allied Countries in Great Britain was held in Cambridge during June 24 and 25, 1944. It was the annual meeting, a sequel to the annual meeting of 1943 held in Oxford, and a special significance was attached to it as a friendly gathering, as well as a business meeting, in view of the not unreasonable expectation that the members may have separated to their own countries before the next annual meeting falls due.

The morning of June 24 opened with meetings of Section IV (Student Affairs), chairman, Prof. R. D. Laurie (Great Britain); Section VIII (Modern Humanities), chairman, Prof. L. E. Genissieux (France); and Section IX (History), chairman, Dr. de Sturler (Belgium). Then all Sections met for a lecture on the history of the Cavendish Laboratory by Sir Lawrence Bragg. The afternoon followed the same pattern: meetings of Section II (Collaboration with International Bodies), chairman, Prof. J. Timmermans (Belgium); Section V (Law), chairman, Prof. B. Helczynski (Poland); Section VI (Science and Technology), chairman, Prof. A. Photiades (Greece); and Section VII (Economy), chairman, Prof. J. A. Veraart (Netherlands), and after tea in the gallery of Emmanuel College a lecture by Prof. G. M. Trevelyan on the history of the University of Cambridge.

On June 25 the General Assembly met, and was welcomed by the vice-chancellor, Dr. T. S. Hele, master of Emmanuel College.

The president of the Association, Prof. J. Timmermans, then gave his address, which was a résumé of the year's work and progress. He pointed out that it has been a period of consolidation but that also there have been new departures. The Executive Committee had found sufficient work to require a meeting each month, with two in May. An Education Conference was held in April on lines similar to that held in the spring of 1943, and the British Council again guaranteed a very considerable contribution towards defraying the cost of publishing the report. The Publicity Committee, under the chairmanship of Prof. Photiades, carried through the publication of *Communication*, addressed to members, of which three numbers have already appeared and of which some half-dozen are planned to be produced during twelve months. Prof. Timmermans reviewed the activities of members of the Executive Committee in relation to other organizations having similar interests, notably the Conference of Allied Ministers of Education, the London International Assembly, the British Association Committee on Post-War

University Education and the International Relations Committee of the Association of University Teachers. One of the most conspicuous developments of interest to the Association during the year was the events following the visit of the American education delegation. This delegation co-operated with the Conference of Allied Ministers of Education in producing a scheme for a United Nations Organisation for Educational and Cultural Reconstruction, which is now under consideration by the United Nations Governments. It is the hope of the Association that it will be able to establish useful contacts with this important Organisation.

Dr. Grayson N. Kefauver, who represents the United States Government in connexion with the development of the United Nations Organisation for Educational and Cultural Reconstruction, was present, and addressed the meeting. He explained the attitude of the United States and the purpose of the new Organization, and welcomed the suggestion of co-operation from the Association of Allied University Professors.

The reports of the various sections were then received by the Assembly, indicating that a considerable amount of work is in hand on a variety of topics. Arising therefrom it was resolved on the recommendation of Section IV that the Memorandum on Student Health which was printed in No. 1 of *Communication* be adopted.

The afternoon session was devoted to a discussion on the draft statutes of the proposed International Association. The importance of a thorough discussion was recognized by all, and it was felt undesirable to proceed to final decisions at this meeting as this was the first occasion on which the General Assembly had had an opportunity of expressing its views. The Executive Committee was asked to undertake some redrafting in the light of the discussion, for presentation to the next general meeting.

Prof. J. A. Veraart (Netherlands) was elected president for the session 1944–45. Other members of the Executive Committee were elected as follows: Belgium, Prof. J. Timmermans; Czechoslovakia, Prof. V. Klecanda; France, Prof. P. Vaucher; Great Britain, Prof. R. D. Laurie; Greece, Prof. A. Photiades; Netherlands, Prof. J. A. Veraart; Norway, Prof. A. Sommerfelt; Poland, Prof. B. Helczynski; U.S.A., Prof. A. L. Goodhart; Yugoslavia, Prof. S. Yovanovic.

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER (temporary) IN PHYSIOLOGY—The Registrar, King's College, Newcastle-upon-Tyne 2 (August 16).

ASSISTANT MASTER to teach SCIENCE SUBJECTS to Junior Technical Classes and to Apprentice Day Classes in the Mill Street School of Building, Manchester—The Director of Education, Education Offices, Deansgate, Manchester 3 (August 16).

SENIOR TECHNICAL OFFICER on the staff of the Northamptonshire Institute of Agriculture, Moulton, Northampton—The Secretary for Education, County Education Offices, Northampton (August 18).

ASSISTANT LECTURER IN METALLURGY—The Registrar, The University, Leeds 2 (August 19).

ASSISTANT LECTURER IN BOTANY—The Registrar, The University, Manchester 13 (August 19).

ASSISTANT MASTER to teach MECHANICAL ENGINEERING SUBJECTS in the Stockton-on-Tees Technical School and Evening Institute—The Director of Education, Shire Hall, Durham (August 19).

SPEECH THERAPIST—The Director of Education, Town Hall, Ilkeston, Derbyshire (August 19).

AGRICULTURAL CHEMIST—The Principal, Agricultural Institute and Experimental Station, Kirton, Boston, Lincs. (August 19).

ASSISTANT PSYCHOLOGIST—The Chief Education Officer, 2 Cecil Road, Bristol 8 (August 21).

LECTURER (temporary) IN PHYSICS—The Registrar, University College, Southampton (August 21).

RESEARCH MANAGER to an Engineering Company in the Midlands (must possess an Honours Degree in either Engineering or Physics)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. A521.XA) (August 21).

CIVIL ENGINEER by an Airways Corporation for Constructional Work in India and Burma—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. E.1069.XA) (August 21).

SPEECH THERAPIST—The School Medical Officer, County Hall, Chichester (August 23).

SENIOR POST under the Aeronautical Inspection Directorate (must possess a Degree in Metallurgy or recognized equivalent)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. F.1155A) (August 25).

ASSISTANT MASTER (Graduate) to teach PHYSICS and some MATHEMATICS in the Sheffield Technical School—The Director of Education, Education Office, Leopold Street, Sheffield 1 (August 26).

READERSHIP IN PHYSICAL ANTHROPOLOGY—The Registrar, University Registry, Oxford (August 31).

SECRETARY to the Editorial Board of the 'Transactions' (must hold a Degree in Physics, Metallurgy or Engineering of a British University, or an equivalent technical qualification)—The Secretary, Institute of Welding, 2 Buckingham Palace Gardens, London, S.W.1 (August 31).

CHIEF ELECTRICAL ENGINEER AND MANAGER—The Town Clerk, Town Hall, Chichester (August 31).

BOROUGH ELECTRICAL ENGINEER AND MANAGER—The Town Clerk, 4 Woodville Terrace, Gravesend, Kent (September 1).

UNIVERSITY CHAIR OF STATISTICS tenable at the London School of Economics—The Academic Registrar, University of London, South Kensington, London, S.W.7 (September 4).

CURATOR OF THE CITY MUSEUMS—The Town Clerk, Room 57, Civic Hall, Leeds 1 (endorsed 'Curator of the City Museums') (September 9).

CHAIR OF ELECTRICAL ENGINEERING—The Acting Registrar, The University, Leeds 2 (September 30).

CHAIR OF BIOLOGY in Victoria University College, Wellington, New Zealand—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, London, W.C.1 (September 30).

LIBRARIAN—The Librarian, Queen's University, Belfast (October 31).

CHAIR OF PSYCHOLOGY in the University of Sydney—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, London, W.C.1 (October 31).

ASSISTANT LECTURER (temporary) IN MATHEMATICS—The Registrar, The University, Sheffield.

ASSISTANT MASTER (Graduate) qualified to teach ENGINEERING SUBJECTS and MATHEMATICS—The Principal, Technical Institute, Beckenham Road, Beckenham, Kent.

TEACHER OF ENGINEERING SUBJECTS (must possess a Degree or equivalent qualification), and a TEACHER (man or woman) OF SCIENCE (with good qualifications in General Science or in Biology)—The Principal, Technical Institute, Darnley Road, Gravesend, Kent.

ENTOMOLOGICAL FIELD OFFICER by the Government of Aden—The Ministry of Labour and National Service, Appointments Department, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. O.S.214).

TEACHER OF ENGINEERING, DRAWING and MECHANICS in the Junior Technical School for Boys—The Principal, Wimbledon Technical College, Gladstone Road, London, S.W.19.

# MACHINERY FOR INTERNATIONAL ADMINISTRATION

ONE of the factors directing fresh attention to the Civil Service at the present time is the realization that much of the success of our plans for dealing with post-war problems will depend upon the way in which the Civil Service carries out its new duties and discharges the much more positive functions which are being demanded of it to-day. That was wel brought out in the debate in the House of Commons on employment policy, and in the report of the Assheton Committee on the Training of Civil Servants. The machinery of government must be adapted to its new tasks. Some re-tooling may be necessary, and it is at least certain that a large part of the Civil Service will require training for its new functions.

While the machinery of government is being re-examined in this way, the administrative problems of international organization have received comparatively little attention. The effectiveness of any system of world co-operation which may be established will not depend, however, solely on the readiness of the nations to co-operate, and their willingness to ensure that the world organization has adequate force at its disposal. It will depend also on whether the system is administratively sound, not merely in point of theory, but also from the point of view of the men and women who will be called upon to make it work. If it makes demands on their loyalty and integrity that are impossibly severe, the system is doomed to failure as surely as if, for other reasons, it fails to command adequate support.

A modest little study has been issued this year by the Royal Institute of International Affairs which seeks to fill this gap. Under the title "The International Secretariat of the Future", it considers the lessons drawn from experience by a group of former officials of the League of Nations, and indicates concisely the problems which will have to be faced at the administrative level whatever form we may give to the policy-making organ or organs or to the committees advising them, especially in technical matters, in the world organization of to-morrow. It shows clearly how the formulation and execution of policy on an international scale require a machine which is capable of being rapidly extended for special purposes, and of being reduced again, without weakening the machine as a whole, when the special activity is completed. A central and permanent secretariat provides the necessary continuity and accumulation of experience and knowledge; but the equally necessary power of expansion and contraction depends on the collaboration of Governments.

Discussing the main aspects of the work of an international secretariat and emphasizing that such a secretariat must develop to the full the technique of collecting and using material which is not likely to be generally available, but which, as a servant of many Governments, it has unique opportunities of securing, the question first asked is whether twenty years experience shows that efficient international

action on the service plane is possible. Without claiming perfection for the League's administrative machine, the writers submit it has been decisively proved by experience that an international Civil Service need not be hopelessly handicapped by the lack of a sufficient *esprit de corps*, and that the difficulty of mutual understanding, the clash of traditional systems and the inequalities of administrative experience, need not render the machine inefficient. If there is agreement on policy, an efficient international service can be organized to carry it out.

If an international service is properly instructed either to execute a particular decision or to study a particular question, or if it is performing a recognized routine of work, the fact of its being internationally staffed is no handicap to its complete efficiency. The importance of this conclusion scarcely needs to be stressed. It means that in our planning for world peace we can take it for granted that an efficient international administration can be set up to carry out our plans, provided that in this field, just as in the greater field of policy, we are prepared to create and maintain the necessary conditions.

The discussion of what those conditions are occupies the greater part of this report. Dealing first with the general framework, the statement postulates that the future international organization will be based largely on the concept of sovereign States. The immediate international issue will consequently continue to be how to promote better co-operation among sovereign entities, not how to abolish them. Success in voluntary co-operation may lead States gradually to transfer more aspects of their sovereignty to the international organization than they are at present prepared to do.

Secondly, the practical impossibility of separating the problems of peace and welfare into watertight regional compartments postulates, or at least points to, the need for a world-wide organization. The report admits, indeed, the value of regional organization for certain technical purposes, though no reference is made to such functional regional developments as the Anglo-American Caribbean Commission or the Middle East Supply Centre. It is concerned rather with the danger that crystallization on regional lines may create vested interests and thus obstruct further developments, apart from the more insidious dangers of isolationism and the doctrine of the *Herrenvolk* which regionalism might foster. A world-wide system, starting with the United Nations and expanding rapidly to include neutral countries and ultimately the ex-enemy countries, is regarded as the most probable and hopeful form of post-war international organization.

Thirdly, the report assumes that the international organization will cover political, economic, health, transport, labour and other welfare and technical questions with an international aspect. The writers of the report, from their own experience, fully endorse the argument of M. R. C. Greaves in "The League Committees and World Order", and maintain that unless political and welfare interests mutually reinforce each other even more than did the political and technical activities of the League itself and the International Labour Organisation, each is likely to fail of its full effect. They do not advocate, however, the immediate creation of a unitary and highly integrated organization complete in all its parts. Effective organizations for security and international justice must indeed be linked to welfare organizations, and it is obviously advantageous and economical to provide common legal, information, translating and other services for the various agencies. Accordingly, individual functional organizations would tend to become linked sooner or later in a general organization, comprising at least a central secretariat and an annual assembly in which all participating States would be represented. Furthermore, since progress in welfare matters can only be secured if peace is assured, the primary and essential duty of an international organization must be to check any tendency towards aggression, and if need be to prevent aggression by force.

The core of this report is to be found, however, in the following two sections which deal more specifically with the international secretariat itself. In regard to loyalty, it stresses the importance of breadth of outlook. The report quotes C. W. Jenks, legal adviser of the International Labour Office: "The international outlook required of the international civil servant is an awareness made instinctive by habit of the needs, emotions, and prejudices of the people of differently-circumstanced countries, as they are felt and expressed by the peoples concerned, accompanied by a capacity for weighing . . . these elements in a judicial manner before reaching any decision to which they are relevant". It is pointed out that experience shows that a spirit of international loyalty among public servants can be maintained in practice and is an essential factor in the activity of an international service.

Representation (in the diplomatic sense) and defence of national interests should not be the function of secretariat officials, and assurance that an official will not be penalized if his duties involve an attitude which is contrary to the policy of his own country on a particular issue is a natural corollary of demanding international loyalty from the service. This point is of particular importance in view of the recommendations in the recent report on the Training of Civil Servants and elsewhere, that selected officers should be seconded for duties with international bodies as one means of redressing the neglect of the experience of other countries which has characterized the British Civil Service. Officials seconded to an international service are particularly vulnerable in this respect.

There are other sound observations on this question of national representation. A system which depends upon the co-operation of member States cannot ignore the factor of national prestige and interest. Representation of all the member States is desirable in itself, both for the contacts it establishes and because it assuages the legitimate desires of Governments; but it ceases to be so unless each official can be usefully employed. It is an important principle that everybody in the service should have constructive work to do, and this principle must be served even if time is required before the expansion of the service

permits full representation on this basis. Beyond this the career must be made as attractive as possible for able persons, and the usual Civil Service principles of permanence, promotion for merit and pension on retirement must be adopted. Similarly, in interchange of personnel between the international and national services, seconding should favourably affect the individual's career in his own service and involve no diminution of his accumulated rights.

The application of these principles, however, must stop short of the highest posts. It should not be made impossible for an exceptionally qualified member of the service to reach these posts, but fresh recruits and interchange of nationals are here of overriding importance. Appointments to the highest posts should be for a limited period, such as seven years, and renewable only in exceptional cases. These responsible posts will be few in number and will command a high premium. A number of them would be reserved in practice for certain nationalities, but while political considerations cannot be entirely disregarded in making such appointments as the head of the service and his deputy, their effect, if possible, should be limited to the enforcement of a wise compromise between the reasons militating in favour of appointing nationals of major or of smaller powers, respectively, to these and other posts in the higher directorate. Apart from other qualifications, moreover, the high officials must be able and willing to work as a team with those above and below them in the service.

It is not easy to define, the report admits, the qualities which the head of the service should possess. He should be young. Political or diplomatic experience, but not necessarily great fame or eminence, is an advantage. Ability for administration in the broadest sense is important, implying a knowledge of when to be dynamic, to take the initiative and to force an issue; when, at the other extreme, to be content as an administrative official; and when, on a middle course, to be a moderator, impartially smoothing over difficulties. These same considerations will apply largely to other members of the high directorate, and in a new organization the only indispensable qualities of the director may well be common sense, courage, integrity and tact.

The central and essential point is that the head of the service and his staff must win the confidence of the member States, and of the policy-making organs which they may set up. In winning this confidence, the abilities and personal qualities of the officials may be as important as the existence of a proper framework within which to operate. As much care must be exercised in selecting the proper people to run the machine as is exercised in creating it; for if able men are not secured, little advance will be effected in world welfare and security however carefully the machinery be planned.

Among the ancillary problems considered in this report is the work of an information section and relations with the Press; and more detailed suggestions for a secretariat information section are included in an appendix. Understanding and support by world public opinion are as essential to the success of an international organization as the co-operation of member Governments. This is true for technical as well as for political questions, and effective publicity is a vital function of the international secretariat, which can do much to establish the atmosphere in which effective international action is possible. This, as Mr. Greaves notes, was one of the most valuable functions of the technical committees of the League of Nations. Similarly, good administration helps to create the internal atmosphere which is conducive to the loyalty of international officials; it will attract able persons to service in the secretariat, ensure the maintenance of good working relations with the national civil services, and reduce considerably the difficulties of collecting members' contribution quotas.

The Royal Institute of International Affairs has done a real service in publishing this study. Attention is directed to some of the problems which need examination and to some preparatory steps which may have to be taken before any new international organization is established. Some of these problems are intimately related to proposals for the reform of national Civil Services, as in Britain. Above all, the report gives a clear and affirmative answer as to the possibility of an efficient international secretariat if the right conditions are created and maintained, and it points equally emphatically to the way in which the effectiveness of international organization depends not only on the quality of the machinery but also on the will to use it. Success can be attained only if individual men and women exercise, through constitutional processes, ungrudgingly and resolutely, their will to use and support the organization and instruments of world order.

## BIOCHEMICAL CANCER RESEARCH

**The Biochemistry of Malignant Tumors**

By Dr. Kurt Stern and Dr. Robert Willheim. Pp. xiv+951. (London: Macmillan & Co., Ltd., 1943.) 60s. net.

MAINLY because of the practical urgency of arriving at a fuller understanding of one of the most insidious diseases, but also because of the theoretical interest of a problem so closely related to the mysteries of animal growth, cancer research has for many years ceased to be the exclusive concern of the clinician and the morphological pathologist. The methods of biochemistry and experimental biology, in the widest sense of these terms, have been increasingly applied, and these sciences may reasonably claim a large share in some of the most hopeful advances of knowledge which have resulted. At present the major contributions appear to be the chemical carcinogens, the chemistry of tumour growth, the filterable agents of certain fowl and rabbit tumours, and the transmission of mammary cancer in mice by the milk-borne cancer agent: all these owe much to the application of biochemistry. More nebulous at present, but offering glittering prizes for the future, are the similar developments in the immunology and laboratory diagnosis of cancer.

These topics must comprise much of any treatise on the biochemistry of malignancy, and they are all surveyed in the present book. So large is the volume of research on these subjects that they alone could easily fill a book of this size; in fact, it is rather surprising that a symposium of this nature has not been published before. Yet, in addition to these major advances, there exists a vast amount of information about the chemistry of cancer, the significance of which is not yet clear and which cannot at present be fitted into any hypothesis concerning the origin and nature of neoplasia. It must regretfully be admitted that there is also a legacy of many years research, much of which is under the grave suspicion of being completely uncritical and technically unreliable.

The scope of the present book is ambitious, in that it attempts to cover the entire field of biochemical investigations connected with the cancer problem in all its aspects. This is a formidable undertaking, and although the result will scarcely satisfy the specialist in any one branch of cancer research, for whom something on the lines of a symposium seems more or less necessary, the authors fully deserve warm commendation for what is undoubtedly a valuable addition to the literature of cancer. The book is all the more welcome since no such compilation in English was hitherto available.

A word about the origin of the present volume may not be out of place. It is based on the extended text of an earlier (1936) German edition by the same authors, both of whom are known for their work in the University of Vienna upon the so-called 'carcinolytic' reaction of Freund and Kaminer. The fact that this reaction is by no means in general favour nowadays need not prejudice the reader against the book, since it is not at all propagandist for any one theory, and the balance of judgment is fairly held throughout; this particular theory not excepted. The present version covers the literature up to the end of 1941 and partially into 1942; the modernization is the work of Dr. Stern, who, in New York, was unfortunately deprived after 1941 of communication with his co-author in the Philippines. To avoid confusion, it may be pointed out that this Dr. Kurt Stern should be distinguished from Dr. Kurt G. Stern, until recently of Yale University, who has also contributed to the biochemistry of cancer.

The classification of the greater part of this book follows the conventional approach of a text-book of biochemistry, although it will be understood that its scope, presentation, and bibliography make it essentially a reference work. This is illustrated by the references to original publications, which appear as footnotes to each page and number from 250 to about 1,000 per chapter. Those that the reviewer has had occasion to consult were all correctly cited. The headings of the chapters indicate the wide variety of topics: inorganic, organic, and physical chemistry; enzymes; nutrition and vitamins; metabolism; hormones. In addition, three highly interesting chapters cover the relevant biochemical features of immunology, chemical and biological tumour diagnostics, and the biochemical aspects of tumour origin and growth. In every subject the treatment is exhaustive, and although not every paper of importance is quoted, nor could this be expected, the omissions are remarkably few, and in almost all fields a very comprehensive picture is presented. It is probably true to say that even the experienced cancer research worker will find many interesting observations recorded here that are unfamiliar to him, or the existence of which he had forgotten. Reference to the excellent subject index will confirm this opinion.

In such a careful and thorough compilation it is a pity that the writing and editing call for some criticism. It should have been a simple matter to eliminate the rather frequent occurrence of un-English phrases, and there is an almost complete absence of sub-headings; for example, the important section on tar and the carcinogenic hydrocarbons as carcinogens occupies thirty pages of solid text without subdivision, in spite of the wide range of topics embraced.

This latter section is perhaps too highly compressed, since it deals with what is undoubtedly an outstanding achievement of cancer research; and the description of the biochemical effects of radium and X-radiation is also very much curtailed. The authors themselves recognize this, and refer the reader in both instances to published reviews. While I sympathize with the difficulty of summarizing what has already been so brilliantly recounted by the original discoverers of the synthetic carcinogenic agents (Kennaway, Cook and collaborators; *Amer. J. Cancer*, **29**, 219–259 (1937); **33**, 50–97 (1938); **39**, 381–582 (1940)), I consider that the balance of the book has been affected by this disproportionately short account. Space for a fuller discussion might perhaps be found by the elimination from other chapters of a number of very dubious earlier references, the claim of which even to historical interest is questionable. In this chapter it is erroneously stated that 1 : 2 : 5 : 6-dibenzanthracene is excreted by the rabbit as the 4′ : 8′-dihydroxy derivative, but not by the rat or mouse (p. 179); in fact, the latter species excrete this derivative, while an unidentified isomeric dihydroxy compound is eliminated in the rabbit. This prompts the suggestion that in general works of this kind the authors would do well to insert the key numbering of the carbon atoms in their published formulæ of polycyclic compounds; otherwise such descriptive names in the text mean little to any but the specialist. In this book, also, formulæ for the carcinogenic azo-dyestuffs might with advantage be included.

The descriptions of the mechanism of carbohydrate metabolism given in Chapter 6 need revising and bringing up to date, and I am not aware of the observation (incorrectly stated to be contained in reference No. 195 on p. 507) that the aerobic glycolysis of chorio(n)epithelioma is abolished when serum is used as the suspension-medium; if true, this would be unique among malignant neoplasms, and as it is this kind of statement that is copied from book to book, it should be correctly quoted. Is it possible that the authors have confused the terms chorionic epithelium and chorion-epithelioma? In any future edition it would be well to emphasize more strongly the loss of specialized metabolic function which accompanies the loss of morphological differentiation in malignant tumours (cf. Dickens and Weil-Malherbe; *Cancer Research*, **3**, 73; 1943).

Perhaps the general recognition of the multiplicity of carcinogenic stimuli is the most characteristic feature of the present stage of cancer research. The problem that still awaits solution is that of correlating these diverse phenomena. Thus, the occurrence of spontaneous mammary cancer in mice is now generally admitted to be determined by at least four distinct factors: the influence of the maternal milk-borne factor, the genetic constitution of the strain, the quantitative and qualitative composition of the diet,

and the effect of hormones, especially the sex hormones. The incidence of breast cancer may be varied almost from zero to 100 per cent by suitable known variations in these factors. On the other hand, in the case of the chemical carcinogens, the effects of the milk factor, hormones, and even genetics appear to be relatively unimportant. The explanation of this apparent paradox, which might perhaps provide a much-needed link between the chemically induced and spontaneous tumours, is an outstanding problem. The claims that filterable tumours can be obtained in fowls by the action of chemical carcinogens lead one to ask if even the milk-borne cancer factor might not also be induced by chemical carcinogens to appear in a strain of mice where its presence cannot normally be demonstrated. No doubt this question will soon be answered, if indeed the experiment has not already been done. The important point is, however, that the progress of the last two decades has made it possible to ask, and to answer, many such questions.

F. DICKENS.

## HIGHER EDUCATION IN ENGLISH-SPEAKING COUNTRIES

**Educational Yearbook of the International Institute of Teachers College, Columbia University, 1943**
Edited by Prof. I. L. Kandel. Pp. xi+297. (New York: Teachers College, Columbia University, 1943.) 3.70 dollars.

THE Educational Yearbook of the International Institute of Teachers College, Columbia University, came into existence twenty years ago, during the whole of which time it has been under the able editorship of Prof. Kandel. The 1943 issue is devoted to higher education in English-speaking countries. At the moment, higher education in all countries is, of course, thoroughly subordinated to the urgent task of winning the War. Nothing else matters. What are usually called the humanities are in a state of suspended animation, and the scientific studies are pursued for utilitarian ends. But in the period following the War, the immediate future of higher education will certainly be one of the most important problems of educational reconstruction. In every country certain questions will inevitably arise. For how many students should higher education be made available ? In what relation does higher education stand to the demands of the modern world ? How can we develop a proper balance between the humanities and the sciences ? What are the relative places of general education and specialization, and what is the relative importance of teaching and research ? Already these questions are being discussed sporadically in magazines and newspapers, both in England and in the United States. This educational yearbook widens the outlook by extending the discussion to all English-speaking countries.

The chapters are placed in alphabetical order, beginning with Australia and ending with the United States of America. As no question of continuity arises, the chapters may be read in any order. Four are assigned to England, six to the United States, and one apiece to Scotland, Ireland, Canada, Australia, New Zealand, South Africa and India. One can well understand the editor's difficulty in enlisting the services of an adequate team of contributors, literally from the ends of the earth, and under war-time conditions. One proof of his success is that most of the chapters are marked by a catholicity of view which sees educational reform in its broad social, and sometimes political, setting. Some of the chapters are interesting and informing as much for the light they throw upon the general situation as for the special purpose for which they are written.

The selected countries present such diversity that no brief summary is possible. In the case of England, the obvious contrast, between Oxford and Cambridge on one hand, and the newer civic universities on the other, raises problems as yet unsolved. It is noteworthy that science has recently made great headway in both the older universities. London stands, as it always has, for religious equality, and it fairly claims to be the first university to admit women to degrees, and the first to give science its due. The chapter on the provincial universities of Britain is one of the most interesting in the book. The Scottish universities, strong in the affections of all classes of the population, present few puzzles to the expositor. Quite the contrary is the case of Ireland, where university education has been complicated from the start by political and religious differences, raising difficulties which have only gradually and as yet partially been overcome.

As for the United States, the general situation at present seems well described by one of the six contributors, who says that the colleges have become armed camps. The journal usually known as *School Life* is replaced by *Education for Victory*; and if this indication is true of the schools, it is certainly true of the colleges and universities. The contributors are quite the reverse of complacent, and post-war reforms are keenly advocated.

In Canada the tendency to educate children in the high schools as if they were all proceeding to universities is being corrected, and the high-school graduate is being "better fitted to meet the demands of modern life". But the outstanding point is that educationally there are two Canadas, representing the British and the French traditions. One of the challenges to the future is that a greater integration be achieved, and "all thoughtful Canadians will agree that, unless the challenge be met, Canadian unity will not be achieved". The report on Australia has many cheering features, but the universities are said to be so "sadly departmentalized" that students who may be trained efficiently for medicine, law, or engineering have no training as citizens, and no interest in the social implications of their professional activities. New Zealand has emerged from the callow stage of reliance upon external examinations conducted from England, but her universities need also to realize the inescapable duty of equipping their students to deal, both as professional workers and as citizens, with the problems of the new world.

A far more tangled problem is that of the Union of South Africa, with its 2,220,000 whites (of whom 60 per cent are Africaners, 35 per cent British and 5 per cent others, mostly Jewish), its 750,000 half-breeds, its 250,000 Indians and its 6,000,000 Africans —fundamental divisions which are reflected in the universities and colleges. Whether Africaner or English in character, the universities are said to remain "the organs of a dominant white group content with the place which it has built for itself at the top of the Union's racial-caste structure". There remains for comment gigantic India, "English-speaking" in the sense that a century ago it was decided that English should be the medium of instruction

in higher education. The dark cloud hanging over the system is the fact of thousands of young men with a university education who are unable to find suitable employment. Signs of a change are, however, discernible. "The old superstition that practical studies were not quite respectable and that technical training was a relatively low type of education is beginning to disappear." The work of the universities needs to be more fully directed to the many problems, human and material, with which the country is faced.

The survey brought together in this modest volume of three hundred pages presents an almost bewildering variety of conditions, and the actual work of the universities and colleges cannot be the same in all the countries included in the survey. One is left in no doubt as to the enormous influence, not always for unmixed good, which places of higher education exert upon a nation's life. The one deep impression which these records leave upon the reader's mind is that in the post-war world the universities must shun the evil of the narrow outlook. When the ancient and the modern, the cultural and the vocational, the humanistic and the scientific, the liberal and the utilitarian, stand rigidly apart, each secretly or openly despising the other, then the fatal narrowness, quite consistent with the utmost dignity and respectability, appears. Always and everywhere, the business of the university is "the education of the whole man".

T. RAYMONT.

## A SYNOPSIS OF INDIA

**India in Outline**

By Lady Hartog. Pp. xiii+110+31 plates. (Cambridge: At the University Press, 1944.) 6s. net.

FOR a general conspectus of India as it is, in most of its aspects, and all comprised in one hundred pages, it would be difficult to find an equal to this little book by Lady Hartog. Its eleven chapters deal with geography and climate, custom and culture, history ancient and modern, the Indian States, natural resources and revenue, industry, administration (including education, public health, etc.), politics, the army, and India's part in the War. There are an appendix consisting of half a dozen compact tables from the 1941 census, a short bibliography, an index, a map, and thirty good photographs well reproduced.

With a scope of this breadth the treatment must be sketchy in the extreme, but the sketch is unbiased, is drawn in admirable proportion, and is surprisingly comprehensive. Inevitably occasional general statements are made which are open to contention. They would no doubt be qualified if there were room for more detailed treatment. One may legitimately doubt whether *purdah* was really introduced by Muslims; or whether the population of India north of the Vindhyas is anything like so distinct from that south of it as Lady Hartog would suggest, for though it is true that purely linguistic differences support her view, anthropological ones are less in her favour. The description of the *ryotwari* system of land tenure as found mainly in the south is scarcely accurate; a *zemindari* system prevails in much of the United Provinces, Bihar and Bengal, but not in the Punjab or Assam. The statement that the cost of the army absorbed about a quarter of the total pre-war revenues of the Government of India is apt to prove misleading to anyone unfamiliar with the division of financial responsibilities between the local and central governments in India. Shellac does not seem to be mentioned among the important commercial products.

The bibliography is disproportionately inclined to the political aspect; short as it is, it might well have included Macdonell's "India's Past" and Blackham's "Incomparable India", while *Great Britain and the East* might perhaps be added to the list of periodicals.

But the fact that there seems little more than that to be said in criticism is in itself high praise. No other outline exists nearly so good to put in the hands of persons ignorant of India and wanting information of every kind in a compact and easily ingested form. Even those who have known India well in pre-war years, but not since war broke out, may learn much from the chapters on India and the War, which bring out well both the remarkable advance which has been made in industry and the narrowness of the margin of India's food supply. In a concise general account of this kind it is far harder to keep due proportion and perspective than on a wider canvas, and the author deserves every credit for an admirable sketch.

J. H. HUTTON.

## PHYSICS AND PHILOSOPHY

**Proceedings of the Aristotelian Society**

New Series, Vol. 43: Containing the Papers read before the Society during the Sixty-fourth Session, 1942–1943. Pp. xxvi+222. (London: Harrison and Sons, Ltd., 1943.) 25s. net.

THIS volume contains, among papers on a wide range of subjects, a symposium on "The New Physics and Metaphysical Materialism" in which the late Prof. Susan Stebbing, Sir James Jeans, Mr. R. B. Braithwaite and Prof. E. T. Whittaker took part (see *Nature*, June 19, 1943, p. 686). Prof. Stebbing in her life-time was convinced that Eddington and Jeans used their standing as scientific men to put across to the public metaphysical views which were thoroughly unsound. In her contribution to this symposium she argues that "the new physics does not imply idealism" (p. 184). If Sir James Jeans thinks it does, it is because he argues, erroneously, that because the wave-picture of the universe is essentially mental, the universe it pictures must be so also.

In answering Prof. Stebbing, Sir James Jeans is led to develop a metaphysic of objective idealism not unlike Spinozism. The particle-picture and the wave-picture both depict reality; one is material, the other mental in its ingredients; therefore reality has a material and a mental aspect.

Mr. Braithwaite out-Stebbings Stebbing in maintaining that the new physics has no relevance for metaphysics. As an exercise in philosophy his paper is the best of the four, but as criticism of Sir James Jeans it is wide of the mark, and what Prof. Whittaker says of Miss Stebbing's contribution would apply equally well to that of Mr. Braithwaite: "It has all the merits and perhaps some of the defects that one would expect to find, say, in a commentary on some of the more mystical poems of Wordsworth by Mr. Bertrand Russell". We may expect this state of affairs to continue until "physicists are philosophers and philosophers physicists".

WINSTON H. F. BARNES.

# THE LIQUID STATE

THE twenty-eighth Guthrie Lecture of the Physical Society was delivered last April by Dr. J. H. Hildebrand, professor of inorganic chemistry in the University of California. He had chosen for his subject "The Liquid State". Prof. Hildebrand is one of the greatest authorities on the physical and chemical properties of solutions, and it is only natural that his vast knowledge and experience in this field have enabled him to tackle the difficult problem of the constitution of liquids on new and promising lines.

Prof. Hildebrand began by outlining and discussing the two conventional methods by which the problem is usually approached: the analogies to the gaseous and to the solid state. A liquid resembles to some extent a compressed gas, and the theoretical treatment of such a model has the van der Waals equation as its basis. However, when we compare the terms of the van der Waals equation with their counterparts in a purely thermodynamic equation of state, we find that it is not possible to fit them with the same constants over any considerable range in the case of liquids. It is, of course, possible to correct the equation by additional constants, but this does not bring us nearer to the desired theoretical interpretation. The customary analogy between the behaviour of gases and liquids as represented by van't Hoff's law for osmotic pressure leads to impossible consequences when concentrated solutions are considered. Instead of describing a liquid as a compressed gas, it can be treated—starting from the other extreme—as a very disordered solid, that is, as a crystal lattice which has been disturbed by the process of melting. This method has been helped to a great extent by the considerable amount of information on the structure of solids at our disposal, and it is a line of approach which offers good prospects for a theoretical interpretation of the liquid state.

Quite a different line of approach can, however, be developed by using a method of interpretation which arises out of the experimental study with the aid of X-rays, and it is on considerations of this kind that Prof. Hildebrand has based his views on the constitution of liquids. The scatter of X-rays in a liquid does not suggest a state of order in any way like that exhibited by a crystal lattice. Its interpretation reveals a short-range order which can be best represented by plotting the average number of molecular centres to be found in the neighbourhood of any given molecule against the distance from this molecule. The number of molecular centres contained in a spherical shell which surrounds the central molecule is given by the volume of the shell, multiplied by the number of molecular centres per unit volume of the substance. This estimate takes no account of the space required by the individual molecules, in so far as it clearly cannot be true for a shell of the order of magnitude of the minimum distance to which two molecules can approach. We must, therefore, introduce a correcting factor which varies with the distance from the central molecule and represents the structure of the liquid. This 'distribution function', $W$, is zero for any distance smaller than the molecular diameter. Beyond this distance we meet the first layer of surrounding molecules and $W$ will be greater than unity. Between the first and the second layer of surrounding molecules, $W$ shows a minimum, rising to a second maximum at the distance of the second surrounding layer. The success of this approach to a general interpretation of the structure

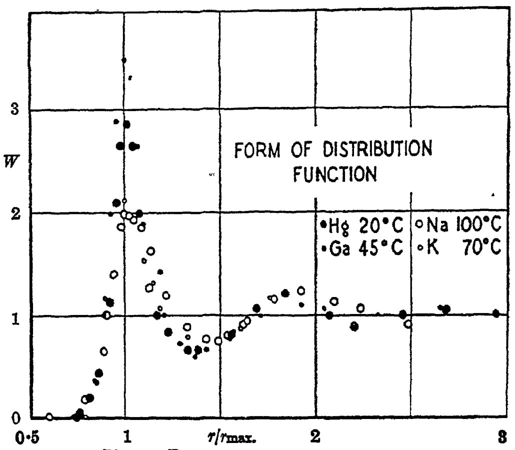

Fig. 1. FORM OF DISTRIBUTION FUNCTION.

of liquids can be gathered from Fig. 1, which shows the distribution function for a number of liquid metals at corresponding states. Here $W$ is plotted against $r/r_{max.}$, where $r_{max.}$ is the position of the first maximum. The figure emphasizes the short range of order encountered in liquids, $W$ remaining practically 1 for distances greater than the radius of the second surrounding shell of particles.

The full significance of this treatment becomes apparent when we consider the forms which $W$ assumes in a solid and in a gas. In the latter case, $W$ rises from zero for distances smaller than that given by the closest approach at collision to the value of 1, which is maintained for all greater distances. In the solid, the long-range order is represented in $W$ by a succession of tall, narrow bands which occur at distances where new groups of molecules will be found. The temperature dependency of the structure becomes apparent by a widening of these bands

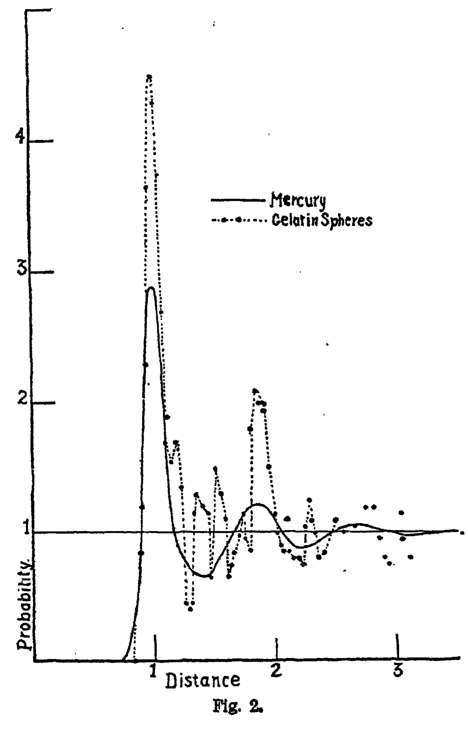

Fig. 2.

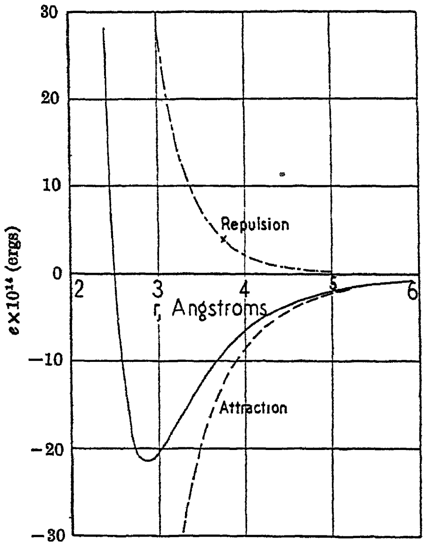

Fig. 3.

caused by the increasing amplitude of vibration of the molecular centres around the lattice points. At the melting-point the bands merge into the 'liquid' curve. With further rise in temperature the state of order in the liquid decreases progressively, the liquid curve flattens more and more, until finally $W$ is unity for any distance larger than the molecular diameter; the gaseous state has been reached. Prof. Hildebrand mentioned an ingenious demonstration experiment on a mechanical model of a liquid which had been carried out at his laboratory. The place of the molecules was taken by a number of gelatine spheres which were inserted in a cubical container, filled with a gelatine solution of the same refractive index as that of the spheres. This made the spheres invisible except for a few which had been coloured. The container was shaken, and the position of the coloured spheres determined by spark photographs. The $W$-function for this system was calculated from the results of these photographs and is reproduced in Fig. 2. For comparison the $W$ function for mercury is superposed.

By combining the known values of the heat of vaporization at different temperatures with the $W$ function, the potential between a pair of molecules of the liquid can be obtained. Splitting the potential into an attractive term $k/r^6$ and a repulsive potential $j/r^n$, the values for $k$, $j$ and $n$ can be found and the potential function constructed. This has actually been done from X-ray results for mercury and the function obtained is given in Fig. 3. A test for the legitimacy of the method was provided by an independent calculation of $k$, which came to $3 \cdot 35 \times 10^{-10}$, a value which is in excellent agreement with that of $3 \cdot 52 \times 10^{-10}$ from the computation based on the $W$-function.

So far, only molecules have been considered which exhibit spherical symmetry in shape as well as in the field of force. There exists an equal maximum state of disorder in all liquids which are composed of spherical molecules, and on passing into the gaseous state they all must suffer the same increase in entropy on evaporation. This is simply Trouton's rule, which holds for all 'normal liquids', and which states that they all have equal entropies of vaporization at the boiling point, or, as Prof. Hildebrand would rather say, at the temperature where the molal volumes of vapour are equal. If, on the other hand, we deal with liquids the molecules of which are very elongated or contain dipoles, we can expect a certain degree of order in the spatial arrangement of these molecules, and the entropy of such liquids will be smaller than that of the completely disordered normal liquids. Since the entropies of all vapours under corresponding conditions are equal, the entropy of vaporization of liquids with non-spherical molecules will be greater than of normal ones. The significance of these exceptions from Trouton's rule is exemplified by the following table, in which the entropy of vaporization at equal molal vapour volumes ($\log R/V = 0 \cdot 1$) is given for a number of liquids.

| Liquid | $\Delta S$ | $\Delta S - 20 \cdot 1$ |
|---|---|---|
| Mercury | 20·1 | 0·0 |
| $C(CH_3)_4$ | 20·1 | 0·0 |
| $i$-$C_5H_{12}$ | 20·2 | 0·1 |
| $n$-$C_5H_{12}$ | 20·7 | 0·6 |
| $n$-$C_6H_{14}$ | 21·5 | 1·4 |
| $(CH_3)_2CH.CH(CH_3)_2$ | 20·3 | 0·2 |
| $CHCl_3$ | 21·7 | 1·6 |
| $(C_2H_5)_2O$ | 21·8 | 1·7 |
| $(CH_3)_2CO$ | 22·5 | 2·4 |
| $C_2H_5OH$ | 27·0 | 6·9 |
| $CH_3OH$ | 26·5 | 6·4 |
| $CCl_4$ | 20·7 | 0·6 |
| $SnCl_4$ | 21·8 | 1·7 |
| $C(NO_2)_4$ | 22·6 | 2·5 |

The second column, giving the differences between the vaporization entropies of the various liquids and that of mercury, denotes their state of order compared with the maximum disorder for spherical molecules. The degree of order which is introduced by alterations in the shape of the molecule is apparent in the differences between the pentanes, between di-*iso*propyl and normal hexane, and finally in the series carbon tetrachloride, stannic chloride and tetra-nitromethane. The deviations from Trouton's rule shown by chloroform, ether and acetone are due to the existence of a strong dipole in the molecule, and to the order created by the mutual interaction of these dipoles in the liquid. It is interesting to see that, though they all have dipole moments of roughly equal strength, the state of order in acetone is considerably greater than in the other two. The explanation is that the dipole in acetone is not buried inside the molecule as in chloroform and ether. The most striking exception, however, is that of the alcohols, and it seems difficult to account for this large deviation by either of the explanations. More information on this point can be gained by dissolving these dipole molecules in non-polar solvents and by observing the change in polarization with concentration. The very strong rise with increasing concentration in the case of the alcohols suggests that the high degree of order in the pure liquid is probably due to the formation of hydrogen bridges.

This is just one example in which the study of solutions aids in the interpretation of the general problem of the constitution of liquids. Thus we can combine observations of the composition of solutions with observations of the vapour phase, which leads us to consider deviations from Raoult's law. This rule states that for a great number of solutions, ideal solutions as they are called, the partial vapour pressure of each component is simply given by the product of its vapour pressure in the pure state and its molar fraction in the solution. Reverting to a description in terms of molecular characteristics, it

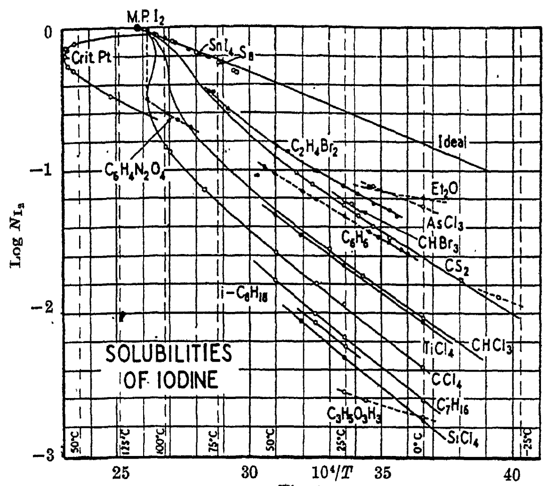

Fig. 4.

means that Raoult's law will hold for mixtures of the same species of molecule, that is, for molecules of equal size, shape and field of force. We can vary this condition by mixing different species and comparing the partial pressures. An interesting case is a mixture of molecules of equal field-strength, but of different size. Here the conceptions of the osmotic school, expressing concentrations in moles per litre, break down. According to these conceptions, we should expect, for example, ethane under one atmosphere to dissolve to the same extent in a given volume of any higher paraffin. On the other hand, the mole fraction of a given amount of ethane in dodecane would be twice that in the same volume of hexane. To achieve the same solubility the pressure of ethane over dodecane would have to be doubled. It is the latter alternative that is supported by the experiment. Normal paraffins of different length such as butane and heptane obey Raoult's law. It simply means that only the space between the molecules of the solvent is at the disposal of the second component, and not the total volume.

The properties of solutions offer almost unlimited scope for obtaining information on the problems of the liquid state. The same considerations as applied to the evaluation of the potential between a pair of identical molecules can be employed in evaluating potentials between molecules of different kind. If we have spherical molecules of equal size, but different molecular fields, the $W$-function is the same as in the pure liquid and can be made the base of calculations. Of the great number of examples given by Prof. Hildebrand, the set dealing with a comparison of different solvents for iodine is perhaps the most instructive one. The solubilities for this substance are given in Fig. 4. Most of the curves belong to one family; they represent 'regular solutions' for which computation on the lines indicated above is possible. They all show the violet colour of iodine vapour, which indicates that the iodine molecules are simply dissolved and have not taken part in chemical changes. The solutions corresponding to the non-regular curves, on the other hand, have different colours and make one suspect that chemical changes have occurred. Prof. Hildebrand directed special attention to the loop intersecting the curve for carbon tetrachloride. Calculation shows that the curve running through the points for the solubility of solid iodine must exhibit an S-shape; which means that there are two compositions in equilibrium at the same temperature. Experiments which had to overcome the difficulty that iodine solutions of such high concentration are quite opaque gave the complete liquid–liquid solubility curve in close approximation with the calculated values.

Results such as this show how far theoretical interpretation of the liquid state can provide an explanation of the observed phenomena, and can even be used in the prediction of conditions of considerable complexity. In his conclusion, Prof. Hildebrand left no doubt, however, that while there are remarkable achievements already at hand, the liquid state still abounds in unexplained phenomena which await elucidation when scientific men can return to its problems after the War.

K. MENDELSSOHN.

# NUTRITION AND A MATTER OF TASTE

By DR. MAGNUS PYKE

DURING the past twenty-five or thirty years the science of nutrition has made very great strides. These advances have been due almost entirely to the application of precise, objective, chemical methods, and have been paralleled by similar advances in other branches of biology. Those who study endocrine secretions can determine, according to his endocrine balance, how the character of a man will be influenced. Similarly, the nutritionist can say from an analysis of the foodstuffs of which a man makes up his diet whether or not, and in what way, his body will be influenced for good or evil. By these means it is now possible to decide, to a greater or less degree of precision, the physiological needs of such divers individuals as pregnant women, adolescent children or coal-miners for calories, protein, fat, four or five mineral substances and six or seven vitamins. In making these advances in knowledge, the subjective feelings of the individuals concerned have not only been neglected; they have specifically been excluded. This has led to several curious conclusions, two at least of which may be cited.

There is, for example, no scientific evidence to suggest that violent muscular work has any influence whatever on the physiological demands of an individual for animal protein; yet there is a widespread popular belief that meat is essential for the efficient prosecution of manual labour. Similarly, so far as the classical nutritionist is aware, onions, garlic and pickles are of negligible nutritional value. Nevertheless, so pressing is the popular demand for such condiments that Britain, faced with extreme pressure on her land for food and aerodromes, is compelled to devote a substantial acreage to their culture.

Now, into the traditional, generation-old field of respectable nutrition comes Prof. Curt Richter, of the Johns Hopkins University School of Medicine*, with a summary of a number of inconvenient papers which have been appearing in the physiological literature during the last ten years, and the implications of which have largely been ignored by nutritionists.

Prof. Richter begins quietly. If rats are kept in a cage on a salt-free diet and given the opportunity of drinking a 3 per cent salt solution out of a graduated tube they will, on the average, drink enough of the

* "Total Self-regulatory Functions in Animals and Human Beings." Curt P. Richter. The Harvey Lectures Series, 38, 63 (1942–43).

solution to provide for their nutritional needs. If the animals are then adrenalectomized, the consumption of the solution of sodium chloride increases enormously even if other solutions are made available. If, on the other hand, the calcium metabolism of rats is disturbed by parathyroidectomy, their appetite for solutions of calcium salts increases and also their desire for salts of chemically related metals such as strontium and magnesium, but not for any other substances.

The next stage of the work was clearly to divide the animals' diet into all its constituent nutrients, and this Prof. Richter did. The rats were placed in cages equipped with several food cups containing, separately, weighed amounts of purified carbohydrate, protein, fat and such materials as dried yeast. Furthermore, they were confronted with from eight to twenty graduated tubes containing measured amounts of solutions of sodium chloride, potassium chloride, calcium lactate, sodium phosphate, magnesium chloride, aneurin, riboflavin, nicotinamide, calcium pantothenate, choline chloride, pyridoxin hydrochloride, biotin, cod-liver oil and any other of the substances it was desired to test.

Some of the results were of surprising interest. For example, when presented with this plethora of choice among substances never normally encountered pure in Nature, and many of which are devoid of any definite taste or smell, not only did the rats choose for themselves a perfect diet, according to the most up-to-date nutritional knowledge, but also they made on their self-chosen diet more economical growth than on a stock diet of non-purified foods. When the rats were depancreatized, they spontaneously avoided carbohydrate and maintained their calories with fat. When the bottle containing aneurin, which is specifically concerned with the intermediary metabolism of non-fat calories, was taken away, the rats reduced their consumption of non-fat calories and ate more fat. When given aneurin but deprived of riboflavin, nicotinamide and pyridoxin, the animals ate more carbohydrate, some fat but almost no protein, thus suggesting that one or other of these vitamins is specifically concerned with intermediary protein metabolism.

Further interesting results were obtained by following the diet which was spontaneously chosen by female rats during the course of pregnancy and lactation. As might, perhaps, have been expected, the calcium consumption rose only slightly during pregnancy but increased very markedly during lactation. An unexpected finding was, however, that the sodium chloride intake increased during pregnancy, and increased again even more substantially during lactation.

What is the application of this line of approach to problems of human diets ? Man has survived for some few thousand years on a self-chosen diet so that, presumably, even without the benefits of academic qualifications in nutrition, he must apparently possess certain powers of discriminating what is good for him. But one has only to look at the physique of the population of a London underground station during an air raid, or notice the enormous incidence of defective teeth among the bulk of even the younger members of the British industrial population, to realize that *laisser-faire* in human nutrition is not enough. Prof. Richter's rats can practise self-selection in their diets when each nutrient is separated from the other. Sir Jack Drummond, on June 27 from the chair of the Nutrition Panel meeting of the Food Group, Society of Chemical Industry, at Burlington House, commented that workmen, who could be demonstrated clinically and biochemically to be deficient in vitamin C, would yet refuse a salad from the best intentioned British *restaurateur*. The explanation may be that if these men had the freedom of choice of the rats, they would select more fat and perhaps sugar than they were getting. Their physiological urge was more likely to be for calories, which, however much vitamin C it might contain, salad signally fails to supply.

Prof. H. Hartridge, at the same meeting, suggested that, fundamentally, the special senses—taste, smell and the others—gave the brain a quick analysis of the blood. If the salt concentration was low there was a craving for salt; if the protein concentration was low, might there not be a craving for, say, meat ? This perhaps was more speculative. These special senses also served to give warnings. On this point, Richter has an interesting experiment to quote. Some of his rats were given the opportunity of drinking their water equally and indiscriminately out of two graduated bottles. To the water in one bottle, very small but increasing concentrations of mercuric chloride were added day by day. When the amount reached 0·003 per cent, which was far too little to exert any physiological effect, the rats suddenly stopped taking the solution from the poison bottle.

Dr. D. R. Davis, of the Psychological Laboratory, Cambridge, also had some interesting comments to make. For example, rats can maintain their calorie needs on solutions of sugar, alcohol and water. When the sugar solution was exchanged for a similar-tasting solution of saccharine, the animals maintained an equal calorie intake by increasing their consumption of alcohol.

Dr. Davis went on to show, however, some of the reasons why whatever biochemical powers of selection man may possess are not sufficient to enable him to dispense with his objective knowledge of nutrition. The first point is 'habituation'. Rats can get used to eating out of a pot placed in a special position and will then fail to select more nutritious food placed in an unfamiliar part of the cage. Animals get 'accustomed' to certain meal-times. Pavlov's experiments with dogs and dinner bells were mentioned here. There was also some discussion of diurnal metabolic variations; but the meeting of the Nutrition Panel seemed quite incapable of coming to any reasonable conclusions about the best meal-times for people working on awkwardly arranged shifts. The palatability of 'appropriate' food was mentioned. To a Briton, sour milk is nasty, and cream-cheese nice; putrid chicken is bad, but putrid pheasant good. Finally, there was the point that people taste with organs other than their mouth and nose. Not only can a blindfolded man not distinguish between a two-penny cigar and a three-shilling one; he rarely knows whether either is alight or not. Dr. Davis cited the example of two chocolates of identical taste and consistency but one white and the other brown. These were rated equally during blindfold tests, but when the examiners could see, they thought the white one 'fatty', 'tallowy' and generally inferior.

Dr. G. W. Scott-Blair showed how many of the ancillary sensations, such as firmness, 'liveliness' and 'body', which combine together with taste to give an individual ideas as to whether or not he likes a food, can be measured mathematically. That the mathematical functions are complicated is, apparently, no

deterrent to the subjective influence on people assessing food. Indeed, they are prepared to compare mathematically incomparable quantities, and provided that they are young and unbiased can, apparently, consistently measure viscosity in terms of elasticity.

But whereas Dr. Scott-Blair tried to explain to a slightly mystified audience of chemists at the Nutrition Panel meeting how to measure in mathematical quantities senses, about which Prof. Hartridge as a physiologist and Dr. Davis as a psychologist had spoken, Mr. R. R. Plowman, an expert and experienced tea-taster, showed how the senses of smell, taste, sight, touch and temperature can, in actual practice, all elegantly be combined.

Evidence which has been accumulating in the literature and much of which was summarized at this meeting of the Nutrition Panel now suggests that the special senses of taste and the rest offer, if used with proper precaution, a fruitful and new method for nutritional research. Richter quotes at least two interesting experiments with human subjects. The first concerns a 3½-year-old boy with undiagnosed destruction of the adrenal cortex. This child kept himself alive for more than two years by eating handfuls of salt. When he was taken under control and fed a 'proper' hospital diet he died. The second experiment is of more general application. A graph was made of the percentage of children between the ages of 5 and 14 years who liked a test sample of cod-liver oil. In general, the frequency decreased as the age increased and as the known physiological needs diminished. The precautions to be exercised when trying to carry out experiments of this nature are many and obvious. Habituation, learnt custom, suggestion, whether visual or of any other kind, are a few. Certain tastes may be exceptional to the rule, if rule it is, that animals, if given the opportunity, will choose the nutrients they need. For example, the nutritionist hitherto has been nonplussed by onions, garlic and perhaps sweetness. Furthermore, people eat food, not nutrients. Nevertheless, it has often been a safe rule when studying industrial nutrition to start from the traditional dietary pattern and try to improve on that, rather than impose a theoretical regime.

The science of nutrition has progressed a long way. It certainly has still a long way to go. Perhaps this meeting of the Nutrition Panel, where nutritionists, chemists, physiologists, psychologists and those forgotten folk who taste and choose and cannot explain, all met to talk together and partially to comprehend each other, may have served in some small way to send it off on a new, fruitful journey.

# THE IMPERIAL COLLEGE OF TROPICAL AGRICULTURE IN WAR-TIME

By Prof. C. W. WARDLAW
University of Manchester

ONCE established, the continuity of British institutions tends to be maintained no matter what the impact of external circumstances may be. In the gloomiest periods of the years 1940–42 it was a feature of life in Britain that bodies concerned with matters of cultural interest were not merely kept in being but in some instances even acquired a new vitality. The publication of the report of the Governing Body of the Imperial College of Tropical Agriculture, Trinidad, for the year 1943, serves to remind us of yet another instance of this continuity of the national effort in the arts of peace, this time in spheres remote from the European conflict—a continuity all the more remarkable in view of the difficulties that lie in the way.

Readers may perhaps recall that the Imperial College of Tropical Agriculture was founded to provide higher instruction in tropical agriculture and in the cultivation and preparation for market of tropical produce of every kind. Practically all members of the Colonial Agricultural Service pass through the College as a first stage, or otherwise have associations with it; thus the bonds that unite past students confer an almost unique unity and coherence to the collective personnel of this Service.

That an effort to maintain the College and its work should be made is not surprising. The developments and improvements that must be effected in agriculture in practically every corner of the Colonial Empire, both as immediate and long-range post-war aims, demand that preparations be put in hand now; and, as we have seen, the Imperial College of Tropical Agriculture is an integral part of the system.

What is remarkable is that it has been possible to keep the establishment actively in being, to continue the recruitment and training of students, to keep the long-term experimental programmes in operation, and to turn out a not inconsiderable body of research. This is a notable achievement; it is something in which we may take a legitimate pride. But it has not been without its rigours, both for staff and students. Most of the academic staff and their families, accustomed to home leave in a temperate climate every two years, have now been continuously in the tropics for six years. Even local travel, which helps to dispel the inescapable tropical *ennui*, has been seriously restricted. There have been periods of food restriction, and even scarcity, more rigorous than at home; and 'digging for victory' in the moist tropics—for that, too, has had to be done—is not quite the same pastime as in our own temperate clime.

Lack of transport provides the clue to the many difficulties. Thus Colonial Office scholars, going out to take the associateship course prior to being posted to different Colonies, have mostly arrived in small batches many months late. For example, the last of those due on October 1, 1942, arrived in the second week of April 1943! As in home universities, the defects of shortened courses have had to be borne. So, too, research work has been hampered by restrictions and delays in the arrival of apparatus and materials.

And so the tale of difficulties mounts up. The near view no doubt suggests a somewhat gloomy picture. But there is clearly another side to it. Agriculture is an art, and art is proverbially long. Nothing is more damaging to agricultural progress than restriction and discontinuity in the scientific research directed towards its improvement. In Trinidad, in spite of all set-backs (and they have been not a few), this essential continuity has been maintained. To those who have held the fort and advanced the tradition of science in its relation to agriculture, under the stress of war, a word of recognition is due.

# OBITUARIES

## Sir Ralph Fowler, O.B.E., F.R.S.

THE death, the tragically early death, of Sir Ralph Fowler in Cambridge on July 28, 1944, at the age of fifty-five, leaves a gap in British and indeed in international mathematical physics which will be hard to bridge in the years that are to come. Whatever Fowler touched, he did well, superlatively well; he was a hard hitter, both at work and games; and he had a quickness of apprehension, and power of plunging into a new subject, of getting abreast of all its details and more than holding his own with it in the presence of its acknowledged experts, at the shortest possible notice, that are exhibited in equal fashion perhaps only in the higher flights of advocacy. He was that rare combination, an accomplished pure mathematician with a sound physical insight. In fact, the only criticism I ever heard of his use of his powers was that he mistook physics as a field for the exercise of mathematical rigour. It was scarcely a fair criticism; only the gruelling training he received in pure mathematics at Cambridge, and the use that he put it to in his early pamphlet on the differential geometry of plane curves, could have given him the experience which was afterwards to mean that no non-rigorous deduction in mathematical physics proper ever escaped his trenchant and sometimes pungently expressed comments. He could make up his mind with lightning rapidity (he was a first-class bridge-player) and his conclusions were always strongly based on common sense, but his mathematical powers ensured that his strokes were savoured with something subtler than mere common sense.

Ralph Howard Fowler was born on January 17, 1889, the eldest son of Howard Fowler, of Burnham, Somerset. He was educated at Winchester (of which he was afterwards a fellow) and at Trinity College, Cambridge, where he was elected to a prize fellowship in 1914 for work in pure mathematics. He already had a commission when he was admitted fellow—I was in chapel at the time, being admitted a scholar, and remember the unaccustomed sight of a gown over an officer's uniform—and while serving as a lieutenant in the Royal Marine Artillery he was seriously wounded in Gallipoli. During convalescence, he encountered A. V. Hill (then a captain in the Cambridgeshires) who was engaged in developing with Horace Darwin what eventually became known as the Darwin-Hill mirror position-finder. The two officers, with the author as assistant, went down to Northolt Aerodrome in March 1916 for the first experiments with this instrument, and there were joined by the late W. Hartree. Thus began A. V. Hill's 'band of brigands' who were to become the A.A. Experimental Section of the Munitions Inventions Department; and thus began R. H. Fowler's interest in mathematical physics. Fowler's main work in the rest of the War of 1914–18 was carried out at Whale Island, under H.M.S. *Excellent*'s hospitality, and besides covering all aspects of the then nascent science of anti-aircraft gunnery, dealt experimentally and mathematically with the fundamental problem of the motion of a yawed shell under aerodynamic forces. These papers, written in conjunction with other well-known mathematicians, and published in the *Philosophical Transactions of the Royal Society*, became classical.

Fowler became a member of the mathematical staff of Trinity in 1919, and turned his attention to the problems of mathematical physics that came to the fore with the return of the late Lord Rutherford to Cambridge as Cavendish professor—problems of kinetic theory, of Aston's mass spectrograph, of collisions 'of the second kind' and the principle of detailed balancing. He also made important contributions to astrophysics. This series of papers developed into a fundamental treatment of problems of statistical mechanics, begun in collaboration with Sir Charles Darwin: evaluations of the enumeration of 'complexions' of a given assembly of similar systems under given external macroscopic conditions, in the forms of coefficients of 'partition functions', were expressed as contour integrals, which in turn were evaluated by the method of 'steepest descents', and led to the identification of a certain mathematical parameter with the absolute temperature, to evaluations of mean energies, mean fluctuations of energy and degrees of dissociation in reversibly reacting constituents. The method was one of extreme generality and power. In essay form it was awarded the Adams Prize of the University of Cambridge in 1925, and in book form it appeared as "Statistical Mechanics", which is now in its second edition and was translated into German. It is a mine of information, of the most detailed kind, on the thermodynamic and quantal properties of dynamical systems in large assemblies—gases (perfect and imperfect), mixed phases, crystals. The first edition contained, too, many astrophysical applications. The work is nowhere easy reading, but its professional competence is amazing. It brought Fowler an international reputation, and led eventually to his joint editorship (with Kapitza) of the Oxford series of Monographs on Physics, and his membership of the editorial board of the newly founded American *Journal of Chemical Physics*.

In the middle nineteen twenties, astronomers had concluded that certain stars, of which the companion of Sirius is the best known, from the evidence of their high-surface temperatures, normal masses and faint absolute luminosities, must have small surface areas and so excessively large densities. It was for some time a mystery as to how matter could exist in this state. In a fundamental paper under the title "Dense Matter", Fowler pointed out that these stars, in their deep interiors, must be examples of ionized gases in the 'degenerate state' to which theoretical physicists had recently been directing attention. This state, differing completely in its physical properties from the classical ideal gas, supervenes under conditions of *relatively* high density and low temperature. The theory was afterwards applied by Sommerfeld to assemblies of electrons in conductors, but to Fowler belongs the credit of first realizing a physical application of the statistical mechanics of degenerate gases.

Fowler was always ready to turn aside to abstract problems of pure mathematics. A notable example was his definitive treatment of the general solutions of the second-order differential equation known as Emden's differential equation, which is of importance in the theory of stellar structure. In 1929 and 1930 there was considerable controversy as to the configurations of a gaseous mass—controversy which is still not settled—and certain empirical results obtained numerically concerning solutions of Emden's equation with non-central boundary conditions attracted Fowler's attention, reminding him of some of his pre-fellowship work. He now found

the clue; and in a set of papers developed a partly geometrical, partly analytical, method of surpassing beauty, which finally classified all solutions of Emden's equation and its generalizations. As G. H. Hardy remarked in a debate on the subject at the Royal Astronomical Society, theories of stellar structure may come and go, but Fowler's contributions to the pure mathematics of the subject have a permanent value.

Fowler had become the mainstay of theoretical physics at the Cavendish, and in 1932 he was appointed to the new Plummer chair at Cambridge. Here he found the fullest opportunity for the exercise of his remarkable versatility and power of assimilating new ideas. Anyone in doubt over an unusual argument, anyone in need of encouraging but salty criticism, always turned to Fowler and came away comforted.

In 1938 Fowler was appointed director of the National Physical Laboratory. But an unexpected illness made it undesirable for him to take up the appointment, and he had the unusual experience of being re-elected to his resigned chair. But he could not be persuaded to reduce his activities. During the present War he undertook important liaison work between British and Canadian science, in Canada, and later he did similar work in the United States. He was created a knight in 1942. Unfortunately, his illness returned, and though he threw himself into further work at the Admiralty, it gradually mastered him. He was attending important conferences up to within a few weeks of his death.

Fowler was elected a fellow of the Royal Society in 1925, and awarded its Royal Medal in 1936. He married Eileen, only daughter of the late Lord Rutherford; she died in 1931. He leaves two sons and two daughters.

Fowler had a forceful, even a masterful personality. As I once put it in a sketch of Fowler for the *Granta*, when Fowler was proctor at Cambridge, he had a short way with any committee he was chairman of, and a short way with the chairman of any committee he was a member of. He could be outspoken to the point of inducing tears, but his subsequent contrition was so endearing that he never left bitterness. He was a man who, starting his scientific career in a promising but by no means excessively distinguished way, went on maturing throughout his life, and attained a fame which surprised even his earliest admirers, but which was wholly deserved, and wholly earned. Had he lived, Fowler would have become one of the greatest scientific powers in the land. He had a tremendous capacity for personal friendships; to collaborate with him on a scientific paper was to embark on high adventure, and the thrill and 'agogness' of working alongside him, when results were being turned out quickly and one was on tip-toes as to what was round the next corner, were things never to be forgotten.

Fowler was big and powerful of frame, and he applied his strength with success to a variety of ball-games. He had claims to distinction as a cricketer, both in batting and bowling; he played an excellent game of both lawn tennis and real tennis; he represented Cambridge at golf and declared (and, we hope, made) many a 'Barnwell no-trumper' on his way home from golf at Mildenhall; he was also a rock-climber.

Fowler was the whole man, of many parts. His life was one of unsparing devotion to high scientific ideals. We cannot over-estimate the loss his untimely death means to Great Britain and to science generally.

E. A. MILNE.

WE regret to announce the following deaths:

Mr. Selskar M. Gunn, vice-president of the Rockefeller Foundation, and formerly director of the Paris office of the International Health Board of the Foundation, aged sixty-one.

Sir Henry Lyons, F.R.S., formerly director of the Science Museum, London, on August 10, aged seventy-nine.

# NEWS and VIEWS

## Prof. T. R. Elliott, C.B.E., F.R.S., and the Beit Trust

MANY generations of Beit Memorial research fellows will hear with regret of the retirement of Prof. Elliott from the honorary secretaryship of the Advisory Board to the Beit Memorial Trustees, an appointment he has held since 1930 when he succeeded the late Sir James Kingston Fowler. The Beit Trust, one of the first great benefactions for medical research in Great Britain, has played a very notable part in the training of a number of skilled investigators who have made important contributions in most branches of scientific medicine. From its inception in 1910, the Trust has been particularly fortunate in its first two honorary secretaries to the Advisory Board, both of whom have been distinguished by their enthusiasm for its work, pride in its achievements and vision in its possibilities. The continuity of the generous policy of the Trust, the ease of its adjustment to changing conditions without any lowering of standards or narrowing of aims, have owed much to their work.

Prof. Elliott, a former Beit fellow (1911–12), became a member of the Advisory Board in 1922, and thus has been able to draw upon his own earlier memories in acting as friend and adviser to many of those he has helped to elect to fellowships. During the last fourteen years his intimate knowledge of the working of the Trust has been of the greatest value to the work of his colleagues on the Advisory Board, and of the Trustees to whom he carried their recommendations. Prof. Elliott will take with him the grateful memories of all who have worked with him on the Advisory Board and of many in all parts of the world who, as Beit Memorial fellows, have had his friendly guidance. He hands on a fine tradition to his successor, Dr. A. N. Drury, director of the Lister Institute.

## Metallurgy at the National Physical Laboratory: Dr. N. P. Allen

DR. NORMAN P. ALLEN, who has been appointed superintendent of the Department of Metallurgy at the National Physical Laboratory in succession to

Dr. C. Sykes, studied metallurgy in the University of Sheffield under Prof. C. H. Desch, graduating B.Met. in 1923 and M.Met. in the following year. He collaborated in research on the die-casting of alloys of low melting point for the Non-Ferrous Metals Research Association, at first in Sheffield and later at University College, Swansea. In 1928 he was appointed to a lectureship in metallurgy in the University of Birmingham, where he obtained the degree of D.Sc. Since 1935 he has been on the staff of the research laboratories of the Mond Nickel Co., Ltd.

Dr. Allen's published investigations, undertaken on behalf of the Non-Ferrous Metals Research Association, have dealt with the effects of gases on non-ferrous metals and alloys, and in a series of papers he has described new methods of examining the solution and release of gases from molten alloys, chiefly of copper, and of the relations between the nature and amount of dissolved gases and the porosity of the resulting ingots and castings. The work involved the design of apparatus for applying both high and low pressures to the alloys when molten, and has been of material help in dealing with problems of porosity in non-ferrous alloys, at the same time providing interesting thermodynamic data.

## Chair of Aviation, Imperial College: Mr. A. A. Hall

THE Department of Aeronautics at the Imperial College of Science and Technology is the largest activity of its kind in the British Empire. The announcement of the appointment of Mr. A. A. Hall as the new head, to succeed Prof. Leonard Bairstow as Zaharoff professor of aviation, is therefore of great interest. Mr. A. A. Hall will be one of the youngest professors in the country. If the course of the War makes it possible for him to take up his new appointment in October 1945 he will then be just over thirty years of age. He comes from Liverpool. Educated at the Alsop High School, Liverpool, and at Clare College, Cambridge, he obtained first-class honours in the Mechanical Sciences Tripos of 1934, with distinction in aeronautics, in thermodynamics, in applied mechanics and in the theory of structures. He was awarded the Rex Moir prize in engineering, the John Bernard Seely prize in aeronautics, the Ricardo prize in thermodynamics, and the Robins prize of Clare College. After a short period at the Royal Aircraft Establishment, he returned to Cambridge with an Armourers and Braziers' research fellowship to pursue aerodynamic research under Sir Melvill Jones and Sir Geoffrey Taylor. The work he did then, on the turbulence in a free stream and on the laminar and turbulent boundary layer, was an outstanding contribution to the subject. He joined the staff of the Royal Aircraft Establishment in 1938 and his activities there have covered a wide field—aerodynamics, wind tunnel design, and jet propulsion, followed since the outbreak of war by investigations on night interception of aircraft and on many scientific and engineering problems in the field of aircraft armament. In all he has shown high qualities of original thought and of leadership—the best augury for his future in a most responsible position.

## Miss Grace Wigglesworth

MISS GRACE WIGGLESWORTH retires in September from the Manchester Museum, where she has served in the Botanical Section as assistant keeper since 1910. An old pupil of the Manchester High School, she entered Owens College in 1900 and graduated B.Sc. with honours in botany in 1903. In the same year "The Victoria University of Manchester" received its title, and Miss Wigglesworth continued her botanical studies in the University as an honorary research fellow until 1907. During this period she published several papers, the first in 1902 in vol. 1 of the *New Phytologist*, entitled "Notes on the Rhizome of *Matonia pectinata*, R.Br.". This was followed by "A Note on the Cotyledons of *Ginkgo biloba* and *Cycas revoluta*" (*Ann. Bot.*; 1903), "The Papillae of the Epidermoidal Layer of the Calamitean Root" (*Ann. Bot.*; 1904) and "The Young Sporophyte of *Lycopodium complanatum* and *L. clavatum*" (*Ann. Bot.*; 1907).

In 1907 Miss Wigglesworth was appointed lecturer in botany at the L.C.C. Clapham Day Training College, but in 1910 she returned to Manchester as assistant keeper in the Museum. She was able to devote some time to research, and further published papers are "The Development of Cœnobia from Resting Spores in the African Water Net (*Hydrodictyon*)", 1928; "A New Californian Species of *Sphaerocarpus*", 1929; and "South African species of *Riella*", 1937. But much important work remains unpublished. She spent several years working on the developmental morphology of *Polytrichum commune*, and has more recently been working on Prof. W. H. Lang's collection of Malayan Hepaticæ. She is a member of the Bryological Society and has an expert knowledge of hepatics. During her period of office in the Museum Miss Wigglesworth has been responsible for the reception, housing and care of the valuable herbaria of Leo Grindon and Cosmo Melvill. Her intimate knowledge of the contents of the Museum has been invaluable to members of the staff of the Botanical Department of the University who have been able to make use of its resources for teaching purposes. Her personal charm and kindliness have endeared her to all who have known her, and her many friends wish her a happy retirement, after a most fruitful scientific career.

## Manchester Joint Research Council

THE vice-chancellor of the University of Manchester and the president of the Manchester Chamber of Commerce have announced the personnel of the Manchester Joint Research Council which is being set up jointly by the Chamber and the University. Representing the University are: Prof. P. M. S. Blackett, Dr. C. T. J. Cronshaw, Prof. D. R. Hartree, Prof. J. R. Hicks, Prof. Willis Jackson, Prof. J. Jewkes, Sir William Clare Lees, Dr. J. E. Myers, Prof. W. E. Morton, Prof. M. Polanyi, Sir Ernest Simon, Sir John Stopford (vice-chancellor), Sir Raymond Streat and Prof. F. C. Thompson. The Manchester Chamber of Commerce will be represented by Mr. J. Harold Brown, Mr. E. A. Carpenter, Mr. J. Curwen, Mr. R. H. Dobson, Mr. John S. Dodd, Dr. A. P. M. Fleming, Mr. H. M. Harwood, Mr. A. H. S. Hinchliffe (president), Mr. Frank Longworth, Mr. L. E. Mather, Mr. N. G. McCulloch, Earl Peel, Mr. C. G. Renold, Mr. A. V. Sugden and Mr. John F. West. The first meeting of the Council will be held at the University on October 9.

## School Certificate Mathematics

A conference of representatives of examining bodies and teachers' associations was held in April 1944 and drew up a new syllabus designed to sweep

away the traditional divisions of the various mathematical subjects studied at the School Certificate stage. The suggested new syllabus, which has now been printed with specimen papers (Mathematical Association), is arranged under seven headings: numbers; mensuration; formulæ and equations; graphs, variation and functionality; two-dimensional figures; three-dimensional figures; practical applications. The main points of it may be summarized as follows. (1) The whole syllabus is designed to bring mathematics more closely into relation with the life and experience of the pupils. (2) It is intended to be alternative to the existing syllabuses and of equal weight. It is not suggested that it has been framed for weaker candidates by any lowering of the standard. (3) The fusion of the relevant mathematical subjects, particularly geometry and trigonometry, should be developed by the setting of mixed papers, three in number each of $2\frac{1}{2}$ hours duration, so that complete freedom of method should be permitted. This freedom should extend to the use of mathematical tables and instruments. (4) To remove much of the emphasis from formal work, only proofs of key theorems should be demanded. From these key theorems many others can be deduced and proofs of these are unnecessary. The Conference admits that the list of key theorems given is not ideal; but it is about the desired length of the essential formal work. (5) Perhaps the most striking feature of the syllabus is the inclusion of the beginning of the calculus, which should grow naturally and easily out of the consideration of graphs. (6) Heavy arithmetical calculations and algebraic manipulation must be excluded. The omission of these will allow the due emphasis needed on the all-important ideas connected with functionality, which begins with graphs and leads naturally to gradients. The whole report is inspiring, and if the basic ideas of it can be successfully carried out, mathematics should indeed become a really vital subject. Too long have we encouraged the blind manipulation of the symbol, with little or no relation to reality, while the deadening influence of the traditional formality in geometry has almost completely obscured the many ramifications of the subject in everyday life. It is to be hoped that this encouraging beginning will lead to the removal of many more artificial divisions in the mathematical honeycomb.

## Ley Farming

"ALTERNATE HUSBANDRY", issued as Joint Publication No. 6 by four of the Imperial Agricultural Bureaux (Aberystwyth. 5*s*.), has been compiled by a number of authors, each of whom deals with different aspects of the subject. It is emphasized that the use of leys in rotation under a wide range of climatic and soil conditions and in combination with a great variety of crops is a question upon which much research is needed, and that the purpose of the publication is largely to provide a basis for that research. The system is flexible, but cannot be applied to all types of agriculture, it being unsuitable, for example, in semi-arid or wet tropical regions where problems of establishment and management multiply considerably. The publication opens with a geographical review in which the trends of development in the practice in fifteen different countries and regions are described. Later chapters deal with the question in detail, showing among other matters that the type of ley selected depends largely on the climatic factor, and that a closer study of the root systems of herbage plants is required before the effect of the various species and their different combinations on the soil can be properly assessed. It is generally recognized that a ley is a method for improving the structure of the soil, as it increases granulation, which both benefits the crop and helps to prevent erosion. Other problems such as weed control, soil conservation, plant health and the economic factors involved in the system are also discussed. As regards the animal crop many factors are involved; but it seems likely that the regular ploughing of grassland will reduce the liability to disease even in spite of increased concentration of stock. For those requiring more detailed information, a list of more than three hundred references are arranged in groups appropriate to each chapter.

## Birth-rate in the United States

ACCORDING to an annotation in the February issue of the *Statistical Bulletin* (the organ of the Metropolitan Life Insurance Company of New York) the War has caused not only a sudden rise in the birth-rate but also very marked though undoubtedly temporary changes in the seasonal pattern of the birth-record. In contrast with the normal pattern of a major peak in the summer months, a minor peak in February and March, and low points about May and December, in 1942 there was a rise in the birth-rate through most of the year with a high peak in December; the accelerated rise in the last quarter of 1942 represented the increased number of conceptions in the period immediately following the attack on Pearl Harbour on December 7, 1941. In 1943 the births were at a maximum in January with a general trend downwards throughout the rest of the year. There was a seasonal dip in May, but births in that month were higher than in November and December. Births in July and August were lower than in each of the first three months of the year and lower than in June. The experience of the last few months clearly shows that a continuing decline of the birth-rate may be expected for the duration of the War, and for at least a year after the cessation of hostilities.

## Irrigation Research in India

THE report for the year 1941 of the Punjab Irrigation Research Institute describes fully the researches on soil grading and soil density, water seepage, movement of silt beds, model investigation of water flow of rivers, weirs and headworks, and land reclamation with particular reference to salt accumulation. In addition to these main researches, many original methods of analysis and measurement are described, and a section deals with the sampling of suspended silt. The volume, which consists of 230 pages and 210 figures or photographs, would be more useful for reference purposes if an index had been provided.

## The Royal Institute of Chemistry

THE Council of the Royal Institute of Chemistry recently decided that the offices of registrar and secretary of the Institute, previously held by Mr. Richard B. Pilcher, should be separated. To the office of registrar, the Council has appointed Mr. R. Leslie Collett, who has for nearly twenty years been assistant secretary, and to the office of secretary, Dr. H. J. T. Ellingham, of the Imperial College of Science and Technology. Both appointments will take effect from January 1, 1945.

## Synthesis of Amylopectin

NATURAL starch is a mixture of two components, which can be separated in a number of ways although it is doubtful if complete separation has yet been attained. The names, amylose and amylopectin, used earlier in a different sense, may be conveniently retained to describe the two components. Amylose, forming about 25 per cent of whole starch, is constituted of unbranched chains of glucose residues, the members being mutually linked by $\alpha$-1 : 4-glycosidic linkages. Amylopectin possesses for the most part the same 1 : 4 glucose linkages and forms about 75 per cent of natural starch, but its chain structure is branched or laminated through the lateral linking of its shorter lengths of 1 : 4 glucose chains by certain $\alpha$-1 : 6-glycosidic bonds.

C. S. Hanes[1] isolated from the potato (and from the pea) a phosphorylase which effected, in the presence of phosphate ion, the conversion of whole starch into glucose-1-phosphate, and demonstrated that this reaction was, in a sense, reversible *in vitro*. The polysaccharide produced in this reverse reaction was not, however, identical with whole starch but with only one of its components. At least 85 per cent of the Hanes' synthetic starch had the properties of an amylose. Thus, (1) it retrograded rapidly from solution, (2) it gave a pure blue colour with iodine, and (3) it was completely hydrolysed to maltose by $\beta$-amylase. End-group assay showed its continuous chain-length to be 80–90 glucose members[2] whereas that of whole starch averages 24–30 units. Furthermore, the molecular weight of the methylated product determined osmotically corresponded to a particle size of 80–100 glucose units, thus providing clear evidence of the absence of branching in this synthetic amylose.

We now have to report the separation from the potato of an enzyme system which catalyses the conversion of glucose-1-phosphate into a polysaccharide which is not amylose but which is probably identical with the amylopectin component of natural starch. This new polysaccharide is constituted entirely of *d*-glucose units, it gives a purple-red colour with iodine, it is soluble in water and does not retrograde from solution. In these properties it is not to be distinguished from the amylopectin fraction of natural starch. Furthermore, it is attacked by $\beta$-amylase and maltose is liberated, but, as with natural amylopectin, the hydrolysis is arrested before the conversion into maltose is complete. This behaviour is characteristic of the branched-chain type and distinguishes it sharply from the unbranched, amylose type which is entirely converted to maltose by $\beta$-amylase. Under identical conditions and by the same preparation of $\beta$-amylase, synthetic amylopectin and natural amylopectin were converted to maltose to the extent of 45 and 49 per cent respectively. These figures represent resting points in the hydrolysis and were attained after about four hours in each case.

In an exploratory experiment, a few grams of the synthetic amylopectin have been methylated and the proportion of end-group assayed. The result quite definitely indicates that the substance is not amylose, inasmuch as the number of glucose residues in the unit chain is 20. We lay no stress on the actual numerical value given for the chain-length because this preliminary assay was carried out on too small a quantity of methylated product to conform to the usual standard of accuracy, and, moreover, the sample submitted to assay contained only 41 per cent methoxyl as compared with the usual 44–45 per cent. The margin of error is not, however, greater than $\pm$ 10 per cent. Although much dubiety is attached to the estimation of molecular weight by viscosity measurement, it may nevertheless be of significance that our viscosity measurements indicate a molecular size corresponding to about 100 hexose units when the $K_m$ constant for methylated whole starch is used. With this reservation in mind, the particle size is seen to be some five times the size of the unit chain, a fact which supports the evidence of branching given by the observation of the cessation of $\beta$-amylase activity at 45 per cent conversion.

Hassid and McCready[3] find for separated natural amylopectin, by end-group assay, a unit chain-length of 25 glucose residues and a molecular weight (by viscosity measurement) corresponding to 450 glucose units. The same experimental error margin ($\pm$ 10 per cent) will apply to this assay figure as to ours for the reason that less than 0·5 gm. of end-group was estimated.

It is our intention to repeat the end-group assay and also to determine the molecular weight by the more trustworthy osmotic method when adequate quantities of synthetic amylopectin become available.

It is too early to discuss the bearing of these observations on the question of starch synthesis in the plant; but we have some reason to believe that Hanes' amylose-synthesizing enzyme participates also in the enzyme system responsible for the synthesis of our amylopectin. It would appear that an additional factor—the *Q* factor—is present in our enzyme preparation which modifies the normal synthetic activity of the phosphorylase (*P* enzyme) and enables 1 : 6-glycosidic cross-linkages to be formed.

It is perhaps important to mention that our synthetic amylopectin cannot be an amylolytic degradation product of an amylose synthesized in the normal way by phosphorylase. We have taken the greatest care to ensure the absence of both $\alpha$- and $\beta$-amylase from our enzyme preparations.

## Penicillinase from *B. subtilis*

IN the bacteriological examination of blood or exudates of patients under treatment with penicillin, it is necessary to inactivate any penicillin present if viable penicillin-sensitive organisms are to grow. The routine testing of penicillin products for sterility also requires a means of neutralizing the antibacterial effect of penicillin. The coli-penicillinase method[1] has the disadvantages that the preparation is turbid and the activity of the final product varies.

Among many chemical and biological materials tested for penicillin-inactivating properties, we have found a strain of *B. subtilis*, previously isolated as a chance contaminant, that was a good source of penicillinase. Our original method was as follows:

24-hour agar cultures in 20-oz. bottles were washed off in a minimum amount of saline. The suspension was then standardized to give an opacity equal to 10 times that of tube 2 of the Brown's opacity tube set. 60 ml. of the suspension were centrifuged for 30 minutes at 5,000 revolutions per minute (radius, 13 cm.). The clear supernatant fluid was decanted and the residual organisms were transferred to an agate mortar and ground for 30 min., when a stained smear showed very few undisrupted bacteria present; 25 ml. of distilled water were added and extraction proceeded at room temperature overnight. After centrifuging until the supernatant fluid was clear (about 10 min.), the deposit was removed and the supernatant fluid was sterilized by Seitz filtration.

Another and a simpler method is to grow the organism in a 100 ml. bottle of papain digest broth at 37° C. for two to three days. The metabolic fluid is then sterilized by Seitz filtration. In preliminary tests 0·5 ml. of the filtrate inactivated 250 Oxford units of sodium penicillin after one hour's contact at room temperature. Control tests showed that the metabolic fluid had no adverse effect on the strain of *Staphylococcus aureus* used as test organism.

showed slight inhibition (in a dilution of 1 : 4) of the test organism.

There is some evidence to show that free formation of penicillinase in the metabolic fluid is marked in penicillin-resistant strains of *B. subtilis*, and that the amount of the penicillinase is related to the strength of the surface pellicle on the culture. Investigations are now being made into the properties of penicillinase produced in agar cultures. The data at present available show that 1 ml. of a dilution of 1 : 250 of the culture fluid still inactivates 50 O.U. of penicillin after four hours incubation. In routine sterility tests the fluid is added to the dried or dissolved samples (for example, to 1 ml. containing 3,000–4,000 O.U.) and left in contact for 24–48 hours at 37° C., after which the penicillin is inactivated. The metabolic fluid kept in the refrigerator over a period of 3–4 weeks shows no deterioration in potency; heating to 80° C. for 30 minutes destroys part of the penicillinase activity.

Penicillinase may safely be added to exudates and body fluids from patients receiving penicillin treatment, for it does not inhibit the growth of bacteria cultivated from such specimens.

The inhibitory effect of penicillinase on penicillin can be clearly shown either in broth tubes using the serial dilution method, or by inseminating agar plates containing penicillin-sensitive organisms; in fact, Heatley's cup method or filter paper disks can be used for estimating penicillinase potency. Alternatively, this can be done by putting the material to be tested on to 'Cellophane' sheets "P.T. 300" on the surface of the agar plates. The penicillinase does not diffuse into the agar and does not pass through the 'Cellophane' membranes as does penicillin, and this permits the test to be easily performed.

+ = 50 O.U./ml. inactivated in 6 hours. ++ = 50 O.U./ml. inactivated in 2 hours

We examined the influence on penicillinase production of different conditions of growth—such as presence of oxygen, carbon dioxide, sugars and serum. Glucose (1 per cent) in papain digest broth decreased penicillinase production, as did 5–10 per cent human serum in the medium. Anaerobic cultivation or growth in 8 per cent carbon dioxide had no direct influence, provided growth of the cultures took place. Penicillinase was produced when the strain was grown in 2 per cent peptone water, but in this medium the addition of glucose did not decrease the amount formed.

The accompanying table summarizes the characteristics of the penicillinase obtained on different media.

The lower *p*H of the glucose broth had no direct effect on the rate of penicillinase production, for in many of our tests with other media we found as much penicillinase to be produced at *p*H 5–6 as at *p*H 7·5. The addition of other carbohydrates (1 per cent starch, mannitol, maltose, lactose) to the medium had a less marked effect in depressing the formation of penicillinase. Although the amount of penicillinase formed with different peptones is similar, it is preferable to use the purer brands, because the metabolic fluid from cruder peptones, containing impurities, showed slight inhibition (in a dilution of 1 : 4) of the test organism.

This work was carried out in connexion with investigations of the Therapeutic Research Corporation of Great Britain.

## Dextran and Levan Molecules Studied with the Electron Microscope

THE fundamentally improved designs for the electron microscope made in recent years by different workers have led to such an improvement in the resolving power that a direct study of giant molecules with the aid of this instrument may contribute in

a certain degree to our knowledge of their appearance. If we except the researches on viruses, the following investigations already performed in this direction should be mentioned: M. von Ardenne[1] and W. M. Stanley and Th. F. Anderson[2] have succeeded in photographing hæmocyanin and edestin; E. Husemann and H. Ruska have also photographed glycogen[3] and iodobenzoylglycogen[4]. All these molecules, however, are more or less spherical ($\phi \sim 100$–300 A.). They therefore appear on the plates as small diffuse dots. The electron-microscopical investigation of these molecules is facilitated by their more compact structure, which gives a good contrast with the substrate. In the case of iodobenzoylglycogen, this contrast has been further improved by the introduction of heavy atoms into the molecule.

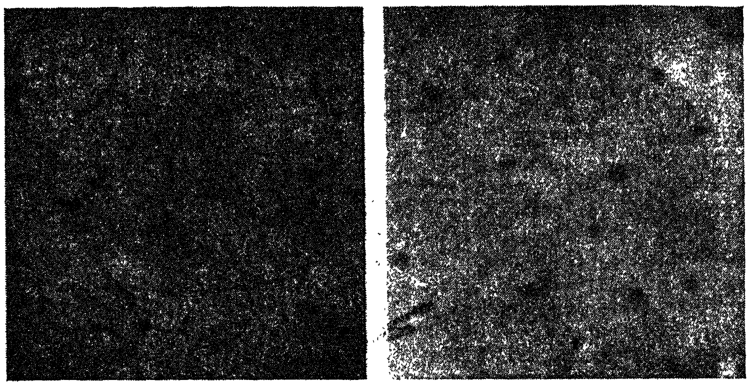

FIG. 1. ELECTRON-MICROSCOPE PHOTOGRAPHS OF (a) DEXTRAN MOLECULES, × 30,000; (b) LEVAN MOLECULES, × 35,000.

In the course of an investigation of the high-molecular components of sugar beet juice, one of us has encountered a polysaccharide of very high molecular weight, dextran[5]. This substance is obtained by the action of a bacterium, *Leuconostoc mesenteroides*, on the juices of the sugar beet, and its composition corresponds to the empirical formula $(C_6H_{10}O_5)_n$. The researches of Levi, Hawkins and Hibbert indicate that the dextran molecule consists of a long principal chain to which side-chains are attached[6]. (Physico-chemical measurements also indicate that the dextran molecule is thread-like[5].) The side-chains may consist each of five glucose units[6]. Since the length of a glucose unit is 5 A., the presence of these side-chains would give the whole molecule a breadth and thickness of 50 A. Consequently it may well be visible under the electron microscope, designed by Prof. Manne Siegbahn, at the Research Institute for Physics in Stockholm, which has a resolving power of about 30 A.

The customary technique has been employed in the electron-microscopical investigation; namely, a dilute solution of the water-soluble dextran (0·002 per cent) was allowed to dry on the foil ($\sim 0{\cdot}008\,\mu$) on the object-holder. The direct electron-optical magnification has been maintained at 7,000 ×, in addition to which the fine-grained plate allows a subsequent enlargement of up to 10 ×. Fig. 1*a* shows the result of such an exposure with total magnification 30,000 ×. On further dilution, pictures are obtained where the dextran threads lie farther apart. The long and branched form of the molecules gives them a strong tendency to cohere, so that in the photograph certain threads may correspond to several molecules lying side by side. In several places, however, extremely thin threads may be distinguished, the thicknesses of which are rather uniform, namely, 30–100 A.; this corresponds well with the estimated molecular thickness of $\sim 50$ A. This estimation of the thickness is naturally quite uncertain in view of the fact that the resolving power of the microscope is just of this magnitude. It is an interesting feature that it is possible, on many different photographs, to distinguish small nodes situated on the fine molecular threads at equal distances from each other, namely, $\sim 800$ A. This phenomenon, unfortunately, is not so evident in the reproductions. The distance between two nodes thus corresponds to about 160 glucose units[7].

We have also taken photographs of levan molecules, that is, polysaccharide molecules built up exclusively of fructose. The levan used by us was prepared from a solution of crude sugar, seeded with a culture of *Bacillus vulgatus*. Investigations performed by one of us with the help of Svedberg's ultracentrifuge showed that this levan has an extremely high molecular weight. Sedimentation constants of the order of 200–300 × $10^{-13}$ and diffusion constants of the order of 0·2 × $10^{-7}$ were measured. If these values are substituted in Svedberg's molecular weight formula, particle weights of the order of 50–100 million are obtained, which values are considerably higher than those usually encountered among soluble polysaccharides. It may well be asked whether these particles with weights of one hundred million may be called molecules. Everything indicates, however, that the particles, despite their size, are stable. The sedimentation constant, for example, is unaltered after the levan has been precipitated with alcohol, dried and redissolved. These experiments with the ultracentrifuge, etc., will be published at a later date by B. Ingelman.

To judge from Fig. 1*b* (total magnification 35,000 ×) these levan molecules would appear to have a more compact structure than the thread-shaped dextran molecules. The particle size varies in a striking manner, which is also to be seen in the ultracentrifugal data. The electron-microscopical photographs indicate, as do the experiments with the ultracentrifuge, an extremely high molecular weight.

## A Simple Fluorometer of the Duboscq Type

VARIOUS fluorometric methods are employed in determining riboflavin and thiamin. The fluorescent substance is freed, and in the final stage is compared with solutions of known concentration. Weisberg and Levin[1] recommended the use of a block-comparator, but later authors[2,3,4] employ a photo-cell connected with a galvanometer for testing the intensity of fluorescence. These photocell arrangements, however, are very expensive.

The method described below is simple and relatively inexpensive. The light-source, a U-shaped Hanovian quartz burner, is projected on to the cups of a Duboscq colorimeter by means of a flask so that each branch of the U-shaped burner illuminates one cup. The fields of the colorimeter are then matched in the usual way and the intensities compared. The advantages of this method are as follows. (1) Both cups are illuminated by the same light-source; therefore changes in the output of light cannot influence the readings. (2) In passing through the liquid the exciting light is partially absorbed; for this reason sample-holders are kept as short as possible in fluorometric work. On the other hand, only low concentrations of fluorescent matter yield a linear response. (3) When illuminating the cups through the window at the bottom, the whole length of the cup cannot be evenly illuminated. In my arrangement, however, the exciting light enters from the front. Hence (*a*) the activating light passes through only the width of the cup (the path thus being rather short); (*b*) the whole length of the cup is evenly illuminated; (*c*) since the cups are viewed through the colorimeter from above, the bright halves of the fields can be easily matched.

The light-source is a 220-volt Hanovian U-shaped burner. The light passes through a Wood's filter to a 500 ml. round-bottom flask filled with distilled water or a saturated solution of copper sulphate (to exclude the red portion of the spectrum transmitted by Wood's filter). If the colorimeter is not fitted with blackened rods, both rods are covered with black varnish and only the bases are left free. The supports of the cups of the colorimeter are copied from the original supports. A ring is soldered on to the support. Then two test-tubes with flat bottoms are fitted into the ring and sealed to it. The size of these tubes depends on the length and diameter of the rods, in our case 60 mm. and 14 mm. respectively. To avoid reflexions, a black ring of about 10 mm. height is painted on the outside of the cups. To protect the eyes an ultra-violet absorbing filter (or an ordinary photographic plate, fixed and bathed in picric acid) is inserted into the eyepiece or between rods and eyepiece.

The estimation of fluorescein is given as an example. (1) Solutions of sodium fluorescein, 0·2, 0·4, 0·6, 0·8, 1·0 and 1·2 gamma/ml., are prepared. (2) Both cups are filled with 0·2 gamma/ml. sodium fluorescein; and the rods are brought to the same position, say, 50 mm. (3) Now a piece of white paper is put up immediately in front of the cups. Then lamp, colorimeter and flask are so adjusted as to project on each cup one branch of the 'U'-lamp. To get an illumination of the whole width of the test tubes, these should be slightly out of focus. Then the paper is removed and the whole arrangement shielded against daylight by a black cloth. By small movements of the stand (but not by moving the rods) a position can be found where both halves of the field are evenly illuminated. Without moving the stand, both rods are now brought to, say, 30 mm.; then again both halves of the field should be equal. Between 0·2 and 1·0 gamma/ml. the relation between scale readings and concentration is a linear one. (4) When determining the concentration of an unknown solution of fluorescein, the unknown is diluted so as to give a fluorescence slightly stronger to the naked eye than the 0·2 gamma/ml. solution. One cup is filled with 0·2 gamma/ml. fluorescein, the other one with the diluted unknown. The rod dipping in the 0·2 gamma/ml. solution is brought to, say, 50 mm. By moving the rod, both fields are matched and the concentration of the unknown read off from a reference diagram.

## Natural Selection in the Six-spot Burnet Moth

THE larva of the common six-spot burnet moth (*Zygaena filipendulæ* L.) forms an elongated cocoon on grass or other stems often at a height of six or more inches above the ground. Sometimes, however, the cocoon is spun on low vegetation or a twig in a hedge.

During last summer, when collecting large numbers of cocoons to breed the parasites, I noted that cocoons affixed to a coarse-meshed wire netting fence bordering a road had often been opened and the contents extracted. This was also the case with cocoons on a hawthorn hedge, but was not so with cocoons on tall upstanding grass stems in the open. The tentative conclusion that the enemy was a bird was confirmed when I saw a great-tit perch on the wire fence, open the end of a cocoon, pull out the larva inside, and thrust it into the mouth of a clamorous young one close by. The damage to this cocoon was similar to that previously noted. Thus it seems that a cocoon is liable to attack by a bird *which can reach it.*

This summer I have taken notes on the fate of all the cocoons on the wire fence for a length of about eighty yards. Each one, as soon as the imago emerged, or after it had been opened, was pulled off the fence and recorded. The results, during May 24–July 10, were as follows: opened and larva or pupa extracted, 22; opened, larva or pupa pecked and damaged but not extracted, 2; moth emerged, 8; moth formed but failed to emerge and died, 2; larva or pupa destroyed by Hymenopterous parasites, 3. Thus out of 37 on the fence, no less than 24 were destroyed by birds—a percentage of 64·8. I had hoped that it would be possible this year also to record the fate of cocoons out of reach of birds, but pressure of work has prevented this, and I have only the unrecorded experiences of last year.

Here is a promising and convenient subject for investigation by school scientific societies, for the

full-fed larvæ are easily found in quantity early in the summer term. A test could also be made of the presence of an instinct in the larva to make its cocoon on a tall waving grass stem rather than on more solid objects, and also whether the larva will be satisfied with any height of stem, or will come down again from one that is too short for safety and seek for a longer one. It is obvious that such an instinct would be selected by attacks such as have been described.

## Stability after the War

THE programme of the United Nations, as broadcast at the end of 1943, may at its briefest be stated thus: the Germans and Japanese are to be defeated and disarmed, and thereafter watched for so long a time as may be necessary by an armed force controlled by the United Nations, who are firmly resolved to remain united.

Historical facts, taken alone, do not predict the future; they do so only if they are combined with some hypothesis. A general form of hypothesis for the quantitative interaction of two entities is a pair of simultaneous differential equations, having time $t$ as independent variable. Almost the simplest of such pairs is

$$dx/dt = g - \alpha x + ky, \qquad dy/dt = h + lx - \beta y, \qquad (1)$$

where $g, h, \alpha, \beta, k, l$, are constants. The most relevant of the quantitative historical facts are the numbers of persons engaged on war-preparations in the opposing groups. Let these be $x$ and $y$. It is then found that the equations (1) are capable of describing the European $x$ and $y$ for the years 1908–13 and again for 1933–38, during the greater part of the arms-races[1]. Moreover, the constants have psychologically intelligible names, thus: $g$, $h$, grievances and ambitions; $k$, $l$, defence coefficients; $\alpha$, $\beta$, fatigue-and-expense coefficients. This analysis emphasizes, what is also obvious to common sense, namely, that if the several nations, now united, were to attempt to regain their former so-called freedom, sovereignty and independence, then after the present War had faded out of mind, disastrous arms-races would be likely to develop between them.

The other essential part of their programme is the submission of the defeated. Equations (1) are too simple to describe defeat or submission. For this purpose it is necessary to introduce at least the quadratic term in the constant $\rho$, which has been called a 'submissiveness', thus[2]

$$\left.\begin{aligned} dx/dt &= g - \alpha x + ky, \\ dy/dt &= h + lx\{1 - \rho(x-y)\} - \beta y. \end{aligned}\right\} \qquad (2)$$

It is very ominous that the turn in the year 1930 from the long pause into the arms-race can be described by equations (2). I am not saying that no other motives were operative. On the contrary, it seems almost certain that the great trade depression and the fading of war-weariness were involved. But I do say that there is no warrant either in those facts or in that theory for the belief that Europe will be permanently stabilized by submissiveness in the presence of grievances, ambitions, defensiveness, and the dislike of fatigue and expense. Balance of power, according to the theory, may be of various types, some stable, some unstable. The need for some other and more binding motive is clearly indicated.

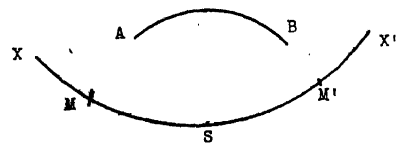
## A Halo Phenomenon

AT 10.15 a.m. G.M.T. on May 2 last some cirrus clouds drifted across the sun; I suspect that they were the remains of condensation trails. As they passed over, I noticed a very peculiar halo phenomenon. The part first visible was the arc $M'X'$; I did not suspect that it was part of a halo circle, though it struck me that it was very like one; I took it to be a long wisp of cirrus or part of a condensation trail. But there then appeared at $M'$ a very brightly coloured parhelion, and at the same time I noticed part of a 22° halo at $A,B$. A few minutes later the arc $X'M'$ had extended through the sun ($S$) to $M$ and $X$; there was another brightly coloured parhelion at $M$; I think that $M$ and $M'$ were rather more than 22° from the sun. The whole phenomenon lasted a very few minutes; I went indoors to get a camera, but by the time I came out again it was all over.



I am quite sure that the arc of the circle through the sun was part of a vertical circle and not part of the horizontal parhelic circle, though like the latter it was white. I am not sufficiently up in meteorological optics to know whether a white vertical circle passing through the sun at its lowest point has been previously observed, but in any event it must be extremely rare. The figure is purely diagamatic; there was no time to take any measurements.

## Centenary of Dalton's Death

THE Manchester Literary and Philosophical Society, which was so closely associated with John Dalton during the whole of his life in Manchester, is commemorating his work on the occasion of the centenary of his death which falls this year. The first meeting of next session is to be devoted to a memorial lecture. In connexion with it the Society hopes to publish a memorial volume in which it would be of interest to give the whereabouts of relics of Dalton, many of those which the Society possessed having been destroyed as a result of fires started by enemy action. The secretaries would therefore welcome any information relating to Dalton's scientific interests or his connexion with the Society. They are also in a position to receive gifts or offers of gifts.

# RESEARCH ITEMS

## Mechanism of Visceral Pain

EXPERIMENTAL morphologists will be interested in the two Lettsomian Lectures on the mechanism of visceral pain delivered by Henry Cohen of Liverpool before the Medical Society of London (see *The Lancet*, 764; June 10, 1944). In the first lecture, Prof. Cohen surveyed and criticized the clinical and experimental data available at present; in the second he discussed the hypotheses which have been formulated to explain why viscera which are normally insensitive to painful stimuli will often reveal themselves by pain in states of disease. None of these hypotheses satisfies Prof. Cohen. It seems necessary, he believes, to postulate a constant stream of subthreshold impulses from the end organs of all pain fibres to the central nervous system, which do not enter central subconsciousness unless central inhibition is lowered. Even an increase in these may not pass the threshold unless it is reinforced by impulses from somatic structures within the same somatic innervation, and vice versa. The metamere, being the phylogenetic unit, renders it unlikely that impulses from any structure within it will reach closely related areas in the sensorium. When any pain impulses, or the sum of them all, rises above the threshold, pain is localized in the segment. If the somatic component of these impulses is cut off, a much stronger stimulus is required in the viscus if pain is to be experienced, and it may then be felt, not only in the segment, but also in the anæsthetized part.

## Life-History of a Mite

STUDENTS of the Acari will be interested in the observations on the behaviour of *Acarus scabiei* made by Dr. Clayton (*Brit. Med. J.*, 752, June 3, 1944) when he placed on the interdigital web between his left thumb and index finger an active female mite. Moving quickly about 1 cm. from the place where it was put, the mite lodged in a furrow of the skin, tilted its body obliquely with the help of its hind-leg bristles and began to bore into the side of the skin furrow. Within a very few minutes "the head and appendages" were buried, but it was 67 minutes before the distal end of the mite had disappeared. J. W. Munro (*J. Roy. Army Med. Coll.*, **33**, 1; 1919) states that, under favourable warm conditions, the mite can conceal itself completely in $2\frac{1}{2}$ minutes. After two full days, the mite observed by Clayton had progressed 0·1 cm. After 24 days the burrow was $\frac{3}{8}$ in. long with perforations in its roof, giving it the typical dotted appearance. In it four translucent eggs were found when it was opened for the removal of the mite. Meanwhile, itching had developed between the middle and ring fingers of the left hand and on the right wrist. A mature female mite was removed from a burrow $\frac{3}{8}$ in. long on the left index finger 34 days after the first mite had begun to burrow. The author does not agree that the posterior direction of the spines of the mite prevent its retrogression out of the burrow and therefore cause its death. He thinks that the spines act as 'pit props' and withstand pressure from the roof and from outside, and help the mite's passage through the skin. There was "strong presumptive evidence" that the eggs of the mite had hatched and that larvæ had migrated and burrowed after slightly less than $5\frac{1}{2}$ days. The author's observations tend to support Monro's statement that the complete life-cycle (egg to egg) varies between $7\frac{1}{2}$ and 13 days.

## Transfusion into the Bone Marrow

IN a paper on transfusion into the bone marrow of the sternum, Hamilton Bailey (see *Nature*, **153**, 258, Feb. 26, 1944) reported favourably on this procedure under certain conditions, and there have been further notes upon this method in the medical literature. Janet D. Gimson (*Brit. Med. J.*, 748, June 3, 1944) now reports on transfusion into the bone marrow of the tibia of infants and young children. The new needle which she has designed for the purpose is figured and described. The technique has been devised because of the difficulty of transfusing into the veins of premature and small infants. The needle is inserted through the flat subcutaneous plate of bone below and medial to the anterior tibial tuberosity well below the epiphysial line of the splinted limb, where there are no important anatomical structures which might be damaged. A photograph of a transfusion in progress is given. Any of the usual transfusion fluids may be given by this method. The constant rate of drip which can be maintained is usually remarkable. The longest time during which one transfusion was maintained was six days, and there was no reason to suppose that it could not have been maintained longer.

## Staining Mammalian Hair

J. Davidson and W. D. Taylor have described (*J. Quekett Micro. Club*, Ser. iv, No. 1, 1943) a technique for the treatment of mammalian hairs so that their structure, more especially that of the cuticular scales, can be studied in detail. Since each species of mammal appears to have its own distinctive hair structure it is easy to see that a means of preparing it for accurate examination may be of importance from the medico-legal point of view as well as for other purposes. The opacity of the medulla in ordinary preparations of hair is shown to be due to the presence in it of air, which can be removed under a vacuum, and not to the presence of pigment. Heavily pigmented hair has next to be bleached, and the formula for a reagent that will do this without injury to the hair is given. The staining is carried out with 1–100 carbol fuchsin (Ziehl Neelson) in a vacuum oven. A series of excellent photomicrographs shows how successful this method is for demonstrating (i) the structure and arrangement of the cuticular scales and (ii) the structure and relative proportions of the cortex and medulla, as shown in optical section, in the hairs of various mammals.

## Enzymatic Adaptation in Yeast

SOME yeasts can ferment galactose whereas others cannot. Of those possessing the ability, some do so only after acclimatization in culture containing the sugar. Some authors claimed that new cells must be formed before the formation of galacto-enzyme occurred, while others suggested that there was a direct cytoplasmic reaction of an original cell. S. Spiegelman, C. C. Lindegren and L. Hedgecock (*Proc. U.S. Nat. Acad. Sci.*, **30**, 13; 1943) have evolved a method by which the reaction of one cell as distinct from that of the population may be followed. It was found that in a haploid population which was presumably heterogeneous, the adaptation to galactose fermentation only occurred after cell divisions, whereas, in diploid-stable populations, this took place throughout the population without the necessity of cell division. A warning is given against the assump-

tion of galactose fermentation taking place when this sugar is the only carbohydrate source for a living yeast colony. Of 34 cultures, only one failed to survive on galactose, but 80 per cent of the cultures were unable to ferment the sugar.

### Genes in Rice

B. S. Kadam and K. Ramiah (*Ind. J. Gen. and Plant Breed.*, **3**, 7; 1943) have listed the inherited characters that have so far been discovered in rice. The number of genes is more than three hundred, and these have been placed under a suitable nomenclature by the authors.

### Synchronous Turbo-Generators

IN a paper (*J. Inst. Elec. Eng.*, **91**, Pt. 2, No. 21; June 1944) on the "Fundamental Electrical Characteristics of Synchronous Turbo-Generators", W. Szwander deals mainly with the MVA. rating or the power factor rating, and with the synchronous-reactance value of large, non-salient-pole machines; and discusses essential factors for selecting these values and a method of making the selection. An analysis is made of the manner in which the two values affect the operation of the generator. From a power chart based on the classical circle diagram, diagrams of 'working area' limitations are derived and represented in co-ordinates of reactive power versus active power, power factor versus active power and excitation current versus active power. These diagrams are suitable for comparing properties of different generators when ordering new units, and for the supervision of operation of generators. Problems of capacitive loads and of synchronous stability of generators are also discussed. From a comparison of external characteristics of an isolated generator, with different load characteristics, conceptions of voltage stability and of 'absolute power limit' in respect of that voltage stability are derived. The author discusses the influence of stator-winding resistance and of saturation on representative diagrams and curves, and illustrates the paper by an example of an actual 50 MW., 58 MVA. turbo-generator.

### Electromagnetic Effects in Solid Iron

IN a paper (*J. Inst. Elec. Eng.*, **91**, Pt. 2, No. 21; June 1944) on "Electromagnetic and Mechanical Effects in Solid Iron due to an Alternating or Rotating Magnetic Field", R. Pohl points out that a problem still awaiting solution is the complete predetermination of the phenomena connected with the penetration of alternating flux into solid iron. The classical expressions for the flux and current distributions and the iron loss due to an alternating magnetomotive force rest on the assumption of constant permeability, and therefore apply only to values of induction far below those now employed. Moreover, they ignore hysteresis, which affects both the loss and the power factor to such an extent as to invalidate these expressions for practical purposes. A further difficulty arises in machine design, in that the magneto-magnetic force acting upon the iron surface forms an unknown component of a known primary magneto-motive force: a second component is absorbed in flux paths outside the iron and depends on the magnitude of the total flux. The paper presents the subject to the designers of electrical machines in a manner with which they are familiar and, in addition to discussing the connexion between the primary ampere-turns and their surface component, shows the effects of hysteresis, and extends the theoretical and experimental investigation to values of induction beyond the knee of the magnetization curve. So far, only the theoretical boundary case of ideal saturation has been solved, and it is shown that a computation based upon a given iron magnetization curve is possible by means of a graphical method. Section 2 of the paper, on practical applications, deals with the utilizable mechanical effects in various types of machines, and indicates means for improving their performance.

### Solar Flares and Magnetic Storms

H. W. NEWTON has continued his work on this subject (*Mon. Not. Roy. Astro. Soc.*, **104**, 1; 1944), discussing the relationship between the less intense flares and geomagnetic activity. The most intense flares of all are denoted by 3+, and, as his earlier paper showed, these proved to be of great importance in the occurrence of great magnetic storms. The present paper is restricted to flares of intensity 3 and 2 in decreasing order of magnitude, and the data for these less-intense flares are almost entirely from the present 11-year solar cycle. Flares of intensity 3 and 2, during 1934–42, are compared with magnetic storms recorded at Greenwich (Abinger), and also with the daily international magnetic character figures (De Bilt). The subject is discussed very fully and is illustrated with the aid of a number of diagrams. In the case of flares of intensity 3, there is a small statistical rise of geomagnetic activity within a few days of the mean flare, but in individual cases the disturbance is generally less intense and is less probable than for flares of 3+. In the case of flares of intensity 2, less than two out of ten flares are associated with a magnetic storm on the day of the flare or one or two days later. This result is very little more than can be expected from pure chance. Fade-outs and magnetic activity are dealt with towards the end of the paper, and the percentage frequency of magnetic storms is plotted against the time-interval in days from fade-out. In a general way the radio fade-out data confirm a small statistical rise of geomagnetic activity within a few days after the mean fade-out. These results are, however, less definite than those from the solar flare data.

### Solar Cycle and Weather

CHARLES G. ABBOT, secretary of the Smithsonian Institution, states that there is close agreement between measurements of calcium flocculi on the sun, made daily by the monks at the Observatory del Ebro, Spain, and changes in the solar constant (*Sky and Telescope*, February). Changes in the solar constant begin two days ahead of changes in the clouds of calcium gas seen on the sun in calcium spectroheliograms. Weather-changes on the earth extend from three days before to seventeen days after the occurrences of the solar changes with which they are correlated. Dr. Abbot finds that for many places the weather features tend to be repeated at intervals of 273 months and still more clearly at double intervals of 546 months, and these characterize the complete cycle of solar constant changes. In addition, the short-interval day-to-day solar variations dominate the weather for many succeeding days. A tentative trial of solar forecasting of temperature departures at Washington for 201 days, based jointly on the work at Ebro and the Smithsonian Institution, gave a correlation coefficient of 59 ± 3 per cent. Dr. Abbot predicts a repetition of the past great North-west droughts in 1975 and again in 2020.

# MAKING AND PRESENTATION OF SCIENTIFIC FILMS

A JOINT meeting of the Association for Scientific Photography and the Scientific Film Association was held at the Ministry of Information on June 24, papers being given by the presidents of the two Associations and by Mr. Geoffrey Bell. Two films were projected, "Control Room" and "Nitrous Oxide-Oxygen-Ether Anæsthesia".

Mr. Arthur Elton, president of the Scientific Film Association, in opening the meeting, welcomed those present on behalf of the two Associations. He said that they could and should be complementary, and that the regions where they overlapped should constitute a strong bond rather than a weakness. He was glad that they were in fact working together and assisting each other materially. To achieve democratic self-government in any country, it is necessary for the citizens to have a knowledge of the scientific processes which govern their lives. The Association for Scientific Photography and the Scientific Film Association are ultimately engaged in public education; while it is not necessarily desirable for everyone to be able to solve a differential equation, the more informed the general public is, the less the danger of its being led away by filibusters such as those who had led away the countries of our enemies.

Mr. Elton then defined the fields covered by the two Associations. The Scientific Film Association, besides seeking to spread the general principles of scientific thought by means of the film, is engaged actively in the more practical problems of the production and distribution of scientific films for the public, and of specialized training films for engineers, chemists, physicists and so forth. The Association for Scientific Photography is concerned with the uses of still photography and cinematography as instruments of scientific research. While the two bodies may appear to be serving separate fields, their functions actually tend to overlap and support each other. For example, a scientific worker might use film in connexion with an investigation, say, for the analysis of high-velocity movements by means of the ultra-speed cine-camera. Sooner or later, he would want to tell people what he had done and therefore to show the film. Unless he was careful his record might well be incomprehensible to all except the specialist. With proper preparation, however, the film could be as useful a method of communication as a published paper. This is where the two Associations overlap most, for they can give advice both on the technique of preparing the film and on its method of presentation and distribution.

Mr. Geoffrey Bell, speaking on "Shooting a Scientific Film", illustrated his talk with "Control Room", a film which was made in Bristol. This shows how the Civil Defence organization works in Great Britain. Though made primarily for American and for general home audiences, the film has also been used for showing to Civil Defence personnel, many of whom did not know how their huge and new organization worked as a whole. The film shows the nature of the technical problems of different branches of Civil Defence and the technique used to achieve co-ordination between these branches. For example, if the telephone engineers and the waterworks engineers want to repair their respective services in the same bomb crater, it is not enough that each should have prepared emergency measures for such a case; there obviously must be co-ordination between the two services. Mr. Bell dealt particularly with the problem of getting this kind of subject-matter converted into film terms. The whole technique of Civil Defence serves in the film as a means of studying the processes of community life, although they are seen in a special light, functioning under the stress of air-raids.

After the film had been screened Mr. Bell pointed out the value of the animated diagram for presenting an abstract process, in this case the procedure by which co-ordination between individual services was achieved through a series of different 'control centres'. He then selected from the film examples of various technical devices and methods of exposition.

One incident was used as typical of the problems of the public services and their relations to the community. The film shows damage to a high-voltage main cable, leaving Avonmouth docks without their normal supplies of electric power. A method of temporary jointing of 33,000-volt cable is shown which takes six hours, instead of the seventy-two hours needed for a permanent jointing. The skill and resource of the electrical engineers is shown to be related directly with the restarting of activity in the docks, and off-loading from ships of essential supplies. Films enable one to show, in a convincing fashion, that detailed aspects of one technical problem can be related with much wider issues affecting the community.

Prof. J. Yule Bogue, president of the Association for Scientific Photography, speaking on "The Production of Scientific Films for Biological and Medical Purposes", divided films into two main groups—those making no new contribution to knowledge but presenting in a suitable form the knowledge at our disposal, and those making a new contribution to knowledge. He then dealt with the former group and followed the making of such a film, from the consideration of its subject-matter for suitability for film treatment, through possible methods of construction, the writing of the script, the photographic techniques involved and the actual shooting of the film, to the cutting, editing and final presentation*.

Prof. Bogue stressed that whether a professional film unit is employed or the film is made by those normally engaged in photography in the department, it was essential to decide all the preliminary work, and to write the complete script, before a foot of film is shot. Although anything scientific implies an orderly presentation of the facts in an objective manner, it is unfortunately true to say that many biological and medical films are neither orderly nor objective although labelled scientific. This is almost always caused by lack of planning and insufficient appreciation of the possibilities of the film.

Prof. Bogue also dealt with the choice of making a film in sound or silent. He believes that, if the worker's or teacher's opinion has to be considered, the film should be silent, but where the film is used to demonstrate a particular scientific discovery or an applied technique by an acknowledged expert in the field, then it should carry a recorded commentary. Having decided this, it is necessary to prepare a full shooting script based on a very clear, short, model lecture manuscript of the subject. Only shots essential to the film should be included, and all camera instructions

* A full report can be obtained from the Secretary, Association for Scientific Photography, Tavistock House North, Tavistock Square, London, W.C.1.

should be clearly given; this requires a full visualization of the finished film while writing the script. When the script is complete, it is highly desirable to send copies to colleagues in the same field for their comments. This usually improves a film very much; it should be noted, however, that two or three outside critics are sufficient and a committee should be avoided.

After a full discussion of the technical details of the filming and of the apparatus used, Prof. Bogue stressed the need for keeping the original film intact and employing a duplicate for cutting and editing, particularly when "Kodachrome" is used. The script should be broken down into shots, each on an index card with full technical information; the editing can then be carried out largely from this file. This is, of course, the stage at which the film is made or spoilt. The best films demand good presentation if they are to be used successfully. A good-quality projector and screen, suitable for the size of hall and audience, are essential.

After the screening of "Nitrous Oxide-Oxygen-Ether Anæsthesia", there was a discussion which ranged over detailed problems of technique in film making, as well as wider issues regarding the production and use of scientific films. Among the matters discussed were the illumination most suitable for the photographing in colour of fatty tissues, and the desirability of making films on specialized subjects about which there might be controversy.

# TECHNICAL EDUCATION IN THE U.S.S.R.

IN a paper read at the fiftieth annual meeting of the Society for the Promotion of Engineering Education (United States), which has recently been published, J. G. Tolpin, of Universal Oil Products Co., described the progress of technical education in the U.S.S.R. up to the end of the third Five-Year Plan in 1942, with special reference to the engineering industries. It is a record of great achievement in the face of many difficulties, and may be viewed as both cause and effect in an unprecedented industrial expansion since 1914; especially since 1931, when Stalin said that Russia was still fifty to a hundred years behind the world's leading nations, and would have to make up this lag in ten years.

In 1914, manufacturing industry was only about one-twelfth its present size, and the whole country was still mainly agricultural. Moreover, the full extent of her vast natural resources was very inadequately realized compared with the knowledge now acquired by research and exploration. For example, it has now been discovered that the reserves of potassium minerals in Kazakhstan are the largest in the world; and the coal seams of the Pechora region are now estimated at 120,000 million tons. These and many other new discoveries of mineral wealth have meant corresponding developments in industrial activity and consequently an ever-increasing and more urgent need for trained and well-educated workers. The following figures indicate some of the progress made since 1913:

| | 1913 | 1937 | 1942 |
|---|---|---|---|
| Coal output (mill. tons) .. .. | 29·1 | 128 | 230 |
| Iron ore ,, .. .. | 9·2 | 27·8 | — |
| Oil (mineral) ,, .. .. | 9·1 | 28·4 | 48·5 |
| Sulphuric acid (1,000 tons) .. .. | 121 | 1,666 | — |
| Electrical energy (bill. kWh.) .. | 1·9 | 36·4 | 75 |
| Locomotives .. .. .. .. | 664 | 1,214 | 2,090 |

In this period the agricultural population, which represented 80 per cent of the whole in 1913, fell to 55·5 per cent of the total in 1939; or, in other words, the non-agricultural wage earners numbered 28 millions in 1938 as compared with 11·2 millions in 1913; total population increased to 170·5 millions in 1939. Industrial output has been stimulated not only through the ordinary channels of better trained workers, but also by special methods and incentives, including the distribution of medals and other decorations for specially good work, mention in the general and technical press, and by other means: at the same time poor results due to bad management or otherwise are equally publicized. The total number of youths of 14–17 at present being mobilized for industrial training is nearly 1,000,000. After preliminary training they will work for four years on State enterprises. In the case of these and possibly other groups, it is said that special inducements are being offered to encourage them to attend the factory technical schools rather than the college grade schools, as the latter do not, it is alleged, turn out quite the right type of skilled workers for industrial plants. In the U.S.S.R., therefore, the old problem met with in other countries of striking a judicious balance between academical and practical or shop training also presents difficulties.

Looking at this matter of technical education and training in more detail, it may be said that the general school organization in the U.S.S.R., like other things in the social system, undergoes constant change, so that, as Tolpin points out, the latest official publication (1940) on school regulations is nearly all new. An important factor in this gradual evolution of the educational policy was the national convention of professors and administrative officers in May 1938, in the Moscow Kremlin, which was attended by Stalin himself. V. M. Molotov then stated that the number of students in college grade schools exceeded the combined figures for Germany, England, France, and Italy, but neither the quantitative nor qualitative objectives had been reached. The total enrolment in all types of schools in 1939 was 34 millions, of whom 600,000 studied in college grade schools. It would scarcely seem that this latter figure is an excessive proportion of the whole, or needed special efforts for its further reduction. There are no sex distinctions, and the Revolution opened all schools equally to men and women, of which the latter seem to have taken full advantage. They are now active in every field of technical and professional work and in all branches of social research. In 1939 sixty per cent of all physicians were women, and in the Bashkir country the percentage reached 75. Many of them are directors of research in medicine and other sciences, pure and applied. Women formed more than 41 per cent of the total of college students in 1939, and 27 per cent in the technical (factory) schools. The most marked advance in this respect has been in the Moslem countries (for example, Uzbekistan and Turkmenia), as might be expected, since in such countries women had much further to travel along the paths to emancipation than in others.

Nor is any distinction made in regard to national minorities or in the numerous parts of the Soviet Union where the native language is not Russian, such as the Ukraine, Georgia, Armenia, White Russia, and parts of Siberia. There are more than a hundred different languages and dialects altogether in the Union, of which more than sixty are recognized for use in public institutions. Many newspapers and

technical journals are printed in these languages, and Russian itself is merely one of the more important subjects of instruction in the schools.

In the early years after the Revolution, schools for adults formed an important part of the Russian educational system, and were strongly supported by the State. Adult students numbered 320,000 in 1932; but the numbers are, of course, gradually declining, as the younger generation, much better educated than its forbears, is growing up. Among all classes of the population—old and young—there is a zeal and keenness for education, stimulated by the teachings of Lenin and other early leaders; but for some time there was a serious lack of suitable teachers. In 1939 the number of professorships or chairs was about 10,000, more than half of which were held in the technical and agricultural colleges; while the total teaching staff was a little more than 40,000. Education is mostly entirely free, and some 90 per cent of the students of college grade schools receive grants.

Special attention is, of course, devoted to vocational training, and the aim is to give at least a minimum of technical training to every worker, including labourers. The Five-Year Plan ending 1942 called for the training of more than 9 million persons for work in industry in different capacities. The technical schools in the Soviet Union, in addition to the higher college grade schools or universities, include also the 'technicums' or secondary technical schools. In 1938 there were in existence 3,400 of these, and it was expected that the number of students would reach 800,000 in 1942. For admission to a 'technicum', seven years of preliminary schooling is required, as compared with ten years for the college grade school; and the course lasts four years.

The factory schools fulfil important functions in training qualified workers. They were reconstituted in a different form in 1940. During the first Five-Year Plan these schools trained 450,000 workers; treble that number during the second; and the number planned for the third was 1,700,000. In addition to purely vocational training, they give a certain amount of general and political education, and also special training designed to meet the needs of any particular industry.

Special facilities, largely controlled by the Committee for Higher Education in Moscow, are provided for a first-class engineering training for students who have taken the general courses in secondary schools and have reached the age of 19–20. These are available either in the universities or technical colleges, and extend over five years, with examinations every year. The programme of study comprises almost the same basic subjects as those of engineering schools in other countries, with a few exceptions. In the case of non-Russian students, ample provision is made for the study of Russian for the first two years, the time being taken out of that allotted for foreign languages. Social and economic science and philosophy are included, with particular reference to that of the Communist Party. Parenthetically, it may be remarked that this philosophy is not necessarily the same as it was in the early days: one of the points most strongly emphasized by Lenin was that social philosophy must be constantly subject to change and evolution, and this appears to have been confirmed in the recent history of the Soviet Union. In regard to foreign languages, it is interesting to note that, until lately at all events, English was the foreign language to be studied by petroleum engineers, whereas German was preferred for mechanical engineers.

Special efforts are made to provide sufficient numbers of the right kind of fully trained teachers for the engineering courses; and no money is spared in buildings and equipment, in facilities for research, and so forth. More attention also is now being given to the matter of patents for invention, with the view of making the patent system a more effective means of encouragement in developing the inventive skill or genius of students. Employment bureaux are an essential part of the organization, but their chief difficulty is that there are always more positions open than applicants to fill them. The 150,000 young engineers and scientific agriculturists trained in more than two hundred technical colleges during the third planned period were certain to be less than the number required. Provision is also made for post-graduate work and preparation for D.Sc., D.Ph. and other degrees. In view of the shortage of trained men just mentioned and the vast programme of rebuilding, etc., at the end of the War, it is thought there may be scope and opportunity for collaboration with British and American engineers, and no doubt this is already under careful consideration in the right quarters.

## NATIONAL RESEARCH COUNCIL, CANADA

THE twenty-sixth annual report of the National Research Council, Canada, 1942–43, includes the report of the president together with the reports of the directors of the Divisions of Applied Biology, Chemistry, Mechanical Engineering, Physics and Electrical Engineering, of the Section on Codes and Specifications and of the Research Plans and Publications Section. Owing to war-time requirements, publication of the "Review of Activities" has been discontinued temporarily. The National Research Council is now serving as a central co-ordinating body directing scientific research in Canada, within its own laboratories, in the universities and in industry, and the Council has been appointed the official research station of the Navy, Army and Air Force in Canada.

With the exception of a long-term project on forest-tree breeding, the work in the Division of Applied Biology is now wholly related to the war effort. The pre-war staff of nine has been increased to twenty-nine to cope with the food problems submitted by various Government departments. Investigations on modified curing practices have led to the adoption of a standard cure, with the result that Canadian bacon is now held in higher favour on the British market than ever before, and even under war-time conditions of transport and storage the proportion of Canadian bacon de-graded by the British Ministry of Food is so exceptionally small that rigorous inspection is no longer considered necessary. Studies on egg-shell treatment to extend the storage life of eggs under the storage and transport conditions of war-time have been completed and large-scale investigations undertaken to determine the best conditions applicable in industry for processing and storing dried eggs. Standard canning procedures in line with the Council's findings have been adopted by manufacturers of canned pork and ham, and a laboratory method has been developed

for processing Irish moss. Work is being continued to find a commercial method for preparing a good gelling substance from this seaweed. Work has been undertaken on improvement of the stability and other properties of lard as a suitable alternative for other vegetable oil shortenings. A survey was made of the vitamin intake of Canadian Army troops garrisoned at district depots, and much work has been done on the development of substitutes for metal containers with special reference to the packaging of dehydrated foods for export or Army use. The Fermentation Section's staff has been increased from four to fourteen members, and much of the time of the Section has been devoted to the study of the manufacture of butylene glycol from wheat by a fermentation process. Pilot plant is under construction.

In the Division of Chemistry, research on photosensitized reactions has continued, but experimental alkaloid research has been on a reduced scale. Fundamental investigations on the chemistry of leather and plastics have continued, and that Section has been considerably enlarged to take care of the test work required by the Armed Services and Inspection Board. The laboratories of the Textile Section were occupied chiefly with defence work involving investigations on substitute materials and preparation of purchase specifications, acceptance tests and fundamental research on problems arising out of war uses of textiles. The Paint Laboratory has been occupied to an increasing extent with the needs of the Services for special paints, lacquers, protective coatings, shell-filling material, anti-freezes, etc. The Rubber Laboratory has given special attention to the study of rubber substitutes and synthetic rubber.

In the Division of Mechanical Engineering, all work having no bearing on the war effort has been suspended or abandoned. Installation of the driving and controlling equipment of the horizontal wind tunnel has been completed, and calibration and adjustment of the vertical spinning tunnel are proceeding. The staff of the Division of Physics and Electrical Engineering has been further increased, and, as before, the bulk of the investigations have been of a secret nature and not at present suitable for publication. The General Physics Section has been engaged largely on naval work, ballistics and the design of fire-control gear, as well as on the development of equipment for one phase of anti-submarine warfare. Work in the Optics Section has involved research and development in optical instruments, photography, spectrochemical analysis and geometrical optics as well as the making of a large number of optical components of military instruments in the optical shop.

The Section on Codes and Specifications has been restricted during the War to a maintenance basis in respect of its two main branches—the National Building Code and the Canadian Government Purchasing Standards Committee. The Research Plans and Publications Section, which is responsible for the conduct of the National Research Council Library, refers to the increasing use of the Library, to its bibliographic work and literature searches, technical inquiry work and the issue of the *Canadian Journal of Research*.

Other details of the war work of the Divisions are included in the president's report, which also gives a survey of extra-mural activities of the Council. Among these may be specially mentioned the Service committees established under the Associate Committee on Medical Research to deal with Aviation Medical Research, Naval Medical Research and Army Medical Research. The first has carried out an impressive programme of work in the fields of high-altitude flying, protective clothing for flyers, oxygen equipment and in special studies relating to personnel selection. The second, in addition to dietary surveys in vessels under operating conditions and in shore establishments, has carried out experiments on the use of vitamin A to improve night vision. Special lighting techniques designed to minimize interference with night vision have been devised for use on bridge controls, bridge instruments and chart tables. Special tests elaborated for the evaluation of night vision, colour vision, and visual acuity have been adopted by the Navy, while experimental work on fatigue of personnel operating anti-submarine detection devices has yielded information which has been applied in determining the watch period to be used for this work. Other investigations have covered under-water blast injury, eye-protection for bridge and look-out personnel, obtaining fresh water from sea-water in lifeboats, protection of naval personnel from noise, combating fatigue in radio detector and wireless operators, and sea-sickness problems. Another war-time committee of the Council has co-ordinated and directed research in Canadian universities on sixty projects concerned with the production of explosives now in use and the development of new explosives.

## THIRD ANNUAL MEETING OF THE ANTI-FASCIST SOCIETY OF SOVIET SCIENTISTS

By VICTOR KRASILNIKOV*

PROMINENT representatives of Soviet science attended the third meeting of the Anti-fascist Society of Soviet Scientists held in Moscow on June 18. In his opening remarks, the president, Derzhavin, reminded his audience of the solemn oath taken by them at their first meeting in the memorable days of October 1941 when the German Army was driving on to the capital of the U.S.S.R. They then vowed to devote all their energy and knowledge to the war effort of the nation. Soviet men of science, he said, have kept that vow.

An eloquent speech was made by the vice-president of the Academy of Sciences, Alexander Baikov. He gave an account of the great contributions of Soviet men of science to the war effort. Metallurgists have speeded up existing processes of production, and introduced important improvements in the technology of iron and steel production. Geologists have discovered new deposits of manganese, mercury, lead and petroleum. Botanists have investigated new varieties of medicinal herbs and vitamin-yielding plants. Agricultural scientists have helped to increase crop-yields. Medical scientists have shown numerous examples of self-sacrificing service to their country.

Prof. Peter Kapitza, of the Academy of Sciences, remarked that since the second meeting of the Society, in July 1943, many stirring and cheering events have taken place. But, while rejoicing at the Army's advance, in the course of which Russian territory is being liberated from the hands of the

* Transcribed and prepared by A. Clifford.

invader, scientific workers cannot but be deeply pained by the damage which the enemy is inflicting on the country. "We scientists have reason to feel gratified by the fact that we have been able to help, with our knowledge, to improve the armaments of the army, and to facilitate the struggle against German barbarity."

The audience listened with great interest to the speech delivered by Prof. Maria Petrova, of Leningrad. She remained in Leningrad all through the siege. "It was painful," she said, "to see how German artillery destroyed the scientific and public institutions of the city, but I never for one moment lost faith that the enemy would be defeated. Work was the best answer to the crimes of the barbarians. During the siege I completed twelve scientific investigations."

Igor Grabar told of the appalling destruction by the Germans of monuments of Russian art in Novgorod and in the environs of Leningrad. Prof. P. V. Pavlov, of the University of Odessa, who lived in that city during its occupation by Germans and Rumanians, and Prof. Alyoshin, of the University of Kiev, who likewise saw all the horrors of German occupation, spoke of the damage done by the invaders to scientific and cultural institutions in the Ukraine. This was also the subject of a speech by Alexander Beletsky, of the Ukrainian Academy of Sciences.

Nikolai Nikolsky, member of the White Russian Academy, told the meeting of the 'new order' in German-occupied Minsk. This elderly grey-bearded scholar escaped from Minsk with the aid of White Russian partisans in August 1943. He had spent seven months with a partisan detachment, and only in April 1944 made his way to the "mainland", as partisans call Soviet territory across the front line. Prof. Krisciunas spoke of the plight of the intelligentsia in German-occupied Lithuania. Nikolai Propper-Grashchenkov, corresponding member of the Academy of Sciences, denounced the practices of German physicians. He said that the Soviet medical profession is in possession of irrefutable proofs of the participation of representatives of German science in the killing of prisoners-of-war and of mentally diseased people, and in the bleeding of Soviet children for blood transfusions to such an extent that the children died. They also have documents showing that German surgeons carried out experimental operations on prisoners-of-war.

Alexander Poraj-Koszyc, another member of the Academy, made an inspiring speech in which he called upon the scientific and professional men of Poland to devote all their efforts to the defeat of Hitlerism.

Many messages of greeting were received from various institutions as well as from private individuals in the Soviet Union and abroad. The meeting enthusiastically adopted the text of a message of greeting to the Commander-in-Chief of the Armed Forces of the U.S.S.R., Joseph Stalin, and issued an appeal to men of science throughout the world. This appeal said, among other things: "Fascism is the most malignant foe of science and culture. . . . There is only one way to save human beings and cultural treasures, and that is, to defeat Germany and her satellites at the earliest possible date. . . . All of us must take an active part in this struggle. Let every intellectual and every scientific worker who is not fighting 'arms in hand' contribute his mite to the common cause of humanity by intense creative effort."

# EARTHQUAKES IN SOUTHERN CALIFORNIA

BENO GUTENBERG and C. F. Richter have recently studied in detail several hundred earthquakes in southern California with the view of finding out the physical properties of the earth's crust in the region. The first paper under discussion, "Recent Results of Earthquake Study in Southern California", by both authors (*Trans. Amer. Geophys. Union*, 1943) contains first the travel-time equations of the district. These are:

$$\bar{P} - 0 = D/5{\cdot}577 \qquad \bar{S} - 0 = -0{\cdot}5 + (D/3{\cdot}26)$$
$$Py - 0 = 1{\cdot}2 + (\Delta/6{\cdot}05) \qquad Sy - 0 = 2{\cdot}0 + (\Delta/3{\cdot}64)$$
$$Pn - 0 = 6 + (\Delta/8{\cdot}06) \qquad Sn - 0 = 8 + (\Delta/4{\cdot}46)$$

where $\Delta$ is epicentral distance in km. and $D$ is hypocentral distance for focal depth of 18 km.

The authors state that the terms independent of $\Delta$ in the equations for $Pn$ and $Sn$ show appreciable variation for shocks in different parts of the region, with maxima of about 9 and 13 respectively in the shocks of northern Owens Valley east of the Sierra Nevada. This is an effect of the 'root' of the Sierra.

The travel-times indicate no variation in the thickness of the 'granitic' layer, which is about 18 km. Most of the shocks originate near the base of this layer. There is at least one 'intermediate' layer between this and the base of the continental crust (the Mohorovičić discontinuity). The velocity of $Py$ in this layer differs notably from that of the similar wave $P^*$ as observed in Europe (6·05 instead of 6·4 km./sec.). If this is a single layer, its thickness varies from about 20 km. in the coastal area to almost 50 km. in the Sierra region.

The term $-0{\cdot}5$ in the equation for $\bar{S}$ represents a frequently noticed discrepancy between the apparent origin-times of $\bar{P}$ and $\bar{S}$. The writers attribute this to development of the fault-fracture with speed greater than the velocity of transverse waves, resulting on the average in early arrival of $\bar{S}$ at the observing stations. The following are mean values of elastic constants (C.G.S. units) from all available data for the region:

| Layer | Bulk-Modulus | Rigidity | Poisson's Ratio |
|---|---|---|---|
| Granitic | $4{\cdot}5 \times 10^{11}$ | $2{\cdot}9 \times 10^{11}$ | 0·24 |
| Intermediate | $5{\cdot}5 \times 10^{11}$ | $3{\cdot}8 \times 10^{11}$ | 0·22 |
| Below Intermediate | $12{\cdot}4 \times 10^{11}$ | $6{\cdot}5 \times 10^{11}$ | 0·28 |

J. M. Nordquist is in the course of developing a new application of the magnitude scale in association with these earthquakes. Assuming a special distribution function already employed by E. J. Gumbel in the investigation of flood-statistics ("Statistical Control-Curves for Flood-Discharges." By E. J. Gumbel, *Trans. Amer. Geophys. Union*, 489–509; 1942) makes it possible to choose a scale for a plot in which the points for various magnitudes fall nearly on a straight line, the level of which is an indication of the degree of activity. This method promises a quantitative definition of seismicity.

The second paper here discussed is "Variations in Physical Properties within the Earth's Crustal Layers", by Beno Gutenberg (*Trans. Amer. Geophys. Union*, 1943). In it the author states that the travel-times as well as the amplitudes lead independently to the conclusion that most of the fifty shocks discussed in this second paper originated at the bottom

of the Granitic layer. In shocks with faulting completely inside the Granitic layer only, the amplitudes of $Py$ should be about the same as those of $Pn$. The fact also that the amplitudes of the various $S$ waves change with distance in a similar way to those of the corresponding $P$ waves indicates that the effect of pressure and temperature on the coefficient of rigidity is relatively the same as on the bulk-modulus.

Gutenberg states that the Mohorovičić discontinuity is at a depth of about 35–40 km. in the coast areas of southern California, but deeper under mountain ranges. The velocity of $Pn$ below it is close to 8·0 km./sec. At first, the velocities of both $P$ and $S$ increase with depth, probably at a rate similar to that in the upper layers; but the rate of increase falls off rapidly with increasing depth, resulting in a rapid decrease of the amplitudes of $Pn$ and $Sn$ with distance beyond $\Delta = 200$ km. Amplitudes of $Pn$ and similarly of $Sn$ in intermediate shocks without appreciable surface waves, on records of shocks originating at various depths within a radius of about 2,000 km. from Huancayo, Peru, and recorded at the station there, confirm results obtained previously by Gutenberg and Richter concerning the relationship between the epicentral distances at which the amplitudes of $Pn$ are very small, and the focal depth of the shocks.

These findings, according to Gutenberg, can be explained on the assumption that at a depth of about 80 km. the melting point of the material is reached. Immediately above that critical depth, the effect of temperature on the bulk-modulus and on the coefficient of rigidity may approach, or even surpass, the effect of pressure. At the critical depth itself, there may be a slight sudden decrease of the wave-velocity. At greater depth, the effect of the temperature on the bulk-modulus and the coefficient of rigidity becomes more and more insignificant. Whereas above the critical depth a certain minimum stress, the strength, is required to start plastic flow, below this depth no appreciable strength exists, and the plastic flow is controlled only by the viscosity of the material.

## FORTHCOMING EVENTS

### Saturday, August 19

ASSOCIATION OF AUSTRIAN ENGINEERS, CHEMISTS AND SCIENTIFIC WORKERS IN GREAT BRITAIN (at Austria House, 260 Oxford Road, Manchester), at 7.30 p.m.—Dr. E. Broda: "Science in Austria (with special reference to the 100th Birthday of L. Boltzmann)".

### Tuesday, August 22

QUEKETT MICROSCOPICAL CLUB (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Exhibition of specimens and discussion.

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

SPEECH THERAPIST (whole-time)—The School Medical Officer, County Hall, Chichester (August 23).

ASSISTANT MASTER preferably with Graduate or equivalent qualifications in Engineering, mainly for work in the Junior Technical School—The Acting Secretary to the Education Committee, 1 Eastbank Street, Southport (August 23).

ASSISTANT PSYCHOLOGIST in the School Psychological Service—The Director of Education, Education Department, Newarke Street, Leicester (August 25).

GRADUATE TEACHER OF ENGINEERING (full-time) for Day and Evening Classes in the Crewe Technical College—The Director of Education, County Education Offices, City Road, Chester (August 25).

LECTURER IN AGRICULTURAL ZOOLOGY, including ENTOMOLOGY, and an ASSISTANT ADVISORY OFFICER IN ANIMAL HUSBANDRY—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow (August 25).

PRINCIPAL OF THE BURNLEY MUNICIPAL COLLEGE—The Director of Education, Education Offices, Burnley (August 26).

ASSISTANT IN BOTANY—The Secretary, The University, Aberdeen (August 28).

ADVISER IN AGRICULTURAL ENTOMOLOGY (temporary)—The Registrar, King's College, Newcastle-upon-Tyne (August 31).

ASSISTANT LECTURER IN ENGINEERING—The Registrar, The University, Manchester 13 (August 31).

LECTURER IN GEOGRAPHY—The Secretary, University of Durham, 38 North Bailey, Durham (September 1).

BOROUGH ENGINEER AND SURVEYOR to the County Borough of Southampton—The Town Clerk, Town Clerk's Office, Civic Centre, Southampton (endorsed 'Borough Engineer and Surveyor') (September 4).

BOROUGH ENGINEER AND SURVEYOR—The Town Clerk, Town Hall, West Ham, London, E.15 (endorsed 'Borough Engineer and Surveyor') (September 4).

LECTURER IN PHYSIOLOGY—The Secretary, The University, Birmingham 3 (September 5).

UNIVERSITY READERSHIP IN PHYSICS tenable at King's College—The Academic Registrar, University of London, South Kensington, London, S.W.7 (September 6).

CHAIR OF MINING—The Acting Registrar, The University, Leeds 2 (September 30).

LECTURER IN PHILOSOPHY—The Very Rev. the Dean, Christ Church, Oxford (October 15).

HYDROGRAPHICAL SURVEYOR for the Basrah Port Directorate, Iraq—The Ministry of Labour and National Service, Appointments Department, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. O.4962S).

SCIENTIFIC OFFICER (man or woman, temporary) in the Cod Liver Oil (Poultry) Standardisation Laboratory—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, Berks.

SPEECH THERAPIST (full-time)—The Secretary for Education, Education Offices, York.

LECTURER (man or woman, full-time, temporary) IN BIOLOGY in the Leeds College of Technology—The Director of Education, Education Offices, Leeds 1.

LECTURER (woman) IN MATHEMATICS AND BIOLOGY (Nature Study) OR GEOGRAPHY in the Swansea Training College for Women—The Director of Education, The Guildhall, Swansea.

## REPORTS and other PUBLICATIONS

*(not included in the monthly Books Supplement)*

### Great Britain and Ireland

Metallurgical Abstracts (General and Non-Ferrous). Vol. 10, 1943 (New Series). Edited by N. B. Vaughan. Pp. xii+523. (London: Institute of Metals.) [257

Medical Research Council. War Memorandum No. 3: Economy in the Use of Drugs in War-Time. Revised second edition; with an Appendix on Economy in the Use of Bactericides. Pp. 16. (London: H.M. Stationery Office.) 3*d*. net. [257

Some Recent Advances in Chemistry in relation to Medicine. By Dr. D. H. Hey. Pp. 24. (London: Royal Institute of Chemistry.) [257

National Veterinary Medical Association of Great Britain and Ireland. Publication No. 6: Report on Diseases of Farm Livestock, Section 2: Diseases of Sheep. Pp. 101. 10*s*. Publication No. 7: Memorandum on Farm Buildings. Pp. 48. 5*s*. (London: National Veterinary Medical Association.) [257

Ministry of Food. Insect Pests of Food. 1: The Larvæ of the Lepidoptera associated with Stored Products, by H. E. Hinton; 2: Keys for the Identification of the Lepidoptera infesting Stored Food Products, by A. S. Corbet and W. H. T. Tams. Pp. 144+5 plates. (London: H.M. Stationery Office.) 5*s*. net. [257

## SCIENTIFIC AND INDUSTRIAL RESEARCH.—I

WHILE there is no interruption to the flow of reports and papers discussing scientific and industrial research—the statements "A Post-war Policy for Science" issued by the Association of Scientific Workers and "Problems of Scientific and Industrial Research" from Nuffield College are among the more recent—there is some reason to fear that even from the point of view of educating public opinion as to what is required, many of the contributions to this discussion are not so effective as they might be. One of the main reasons is that discussion, not to say opinion, is becoming confused because of the failure to distinguish clearly between tactics and strategy. Admittedly the distinction is not always easy to maintain in practice, but it is all the more important that the effort should be made at a time when the short-term and long-term aspects of these problems may vary considerably in urgency. Unless our broad objectives are clearly seen and defined in terms both of programmes and in respect of the type of men required to serve them, there is grave danger that steps may be taken to meet our short-term needs which may prove serious obstacles to the more fundamental developments which are also required.

There is yet another reason for distinguishing clearly between the tactics and the strategy of research which is well illustrated in the Nuffield College statement. Welcome as may be the large measure of agreement on what are clearly matters of tactics, such as the encouragement of mobility in research workers, on their status and remuneration and general improvement in conditions of service, such matters depend on, and may even determine, the nature of the institutions or organization which we set up for research. Unless, therefore, we have first resolved on the broad lines of our research programmes and on the qualities which they will demand in the personnel responsible for their execution, apart from the corresponding demands for material resources such as equipment, we cannot determine the appropriateness of either institutions or organization to serve our purposes. Attention to tactical questions before strategic objectives have been decided may thus very well create obstacles to the strategy of research which will not easily be overcome.

There is a further reason why the distinction between strategy and tactics is important, and this is well illustrated in the statement from the Association of Scientific Workers. The decline of German science since 1933 is sufficient evidence that science cannot ignore political institutions, that, even from the point of view of the advance of science itself, some regard must be had to the social and political institutions affecting the conditions under which the man of science works. Society has an effect on the course of science which may not be so obvious, but may be as pronounced, as the impact of science on society. Not only are scientific workers increasingly concerned

with the social effects of the application of scientific discoveries, with seeing that the knowledge which in such fields as nutrition, for example, has made possible the improvement of health and elimination of disease, is used effectively, but also they are conscious that the structure of social institutions and of industry may markedly assist or impede such processes.

With such considerations increasingly prominent, the difficulty of handling aright the problems which arise out of the interactions of science and society and politics becomes more acute. It is more than ever important, as it becomes more difficult, to draw the line and determine exactly how far and in what manner science should make its representations in political affairs where scientific factors are specially important. Uncertainty of touch or judgment in such matters as, for example, in the statement from the Association of Scientific Workers, is a fatal obstacle to handling these problems wisely and shaping aright the organizations through which may best be expressed the voice of science in the fields where it has a legitimate and imperative right to be heard.

One of the main reasons for failings in this respect is the absence of enough attention to the philosophy of research, and the symposium on the "Organisation, Direction and Support of Research" arranged last autumn by the American Philosophical Society (see p. 263 of this issue) is a notable contribution to the fundamental thinking required, here and on the larger strategy of research, before we can consider in detail those questions of tactics with which much current discussion in Great Britain has been overburdened. The long paper by H. A. Innis on "Political Economy in the Modern State" contributed to that symposium is particularly suggestive in this connexion, and a welcome correction alike to the tendency to align science with any particular political party or system or to those who imagine that science can remain indifferent to the political institutions which determine the limits within which freedom of scientific thought and inquiry are possible. He directs attention to exactly those problems which must be solved in the control of research, whether by the State or by industry, if the creative spirit is to be preserved and if freedom of inquiry is to mean advance in knowledge and not the mere acquisition of information which may or may not be relevant to future intellectual progress or to society's needs.

Recognition that the distinction between fundamental and applied research is merely a convenience which can be overstressed should at least help the consideration of the conditions which are fundamental for fruitful research of either type. In many fields, as the Nuffield College statement points out, the distinction has little meaning. Both methods are constantly being used simultaneously in attacking a problem ; they are interdependent, advance in one constantly affecting the other. No clearer demonstration of this could be found than in the recent offer of the directors of Imperial Chemical Industries, Ltd., to provide eighty fellowships in science at nine universities in Great Britain, in connexion with which Lord McGowan stated, "Nearly three generations of experience of the administration and conduct of research have convinced us that academic and industrial research are interdependent and complementary and that it is useless to expect substantial advances in industry without corresponding advances in academic science". Clearly, therefore, if we can determine and establish the conditions under which fundamental research or investigation concerned purely with the advancement of scientific knowledge is best promoted, we shall have gone far to determine those under which applied research also will flourish, and this irrespective of any particular branch of scientific inquiry. We cannot, however, rest content merely with postulating a free society and freedom of inquiry. The research worker must be free both from intimidation and from control by government ; he must be able to inquire and speculate with as few restraints as possible : but the debate between the protagonists for absolute freedom in science and those who advocate the maximum planning of science will lose some of its value if it fails to emphasize the positive as well as the negative side. We are concerned with factors which stimulate, as well as with avoiding restrictive or repressive conditions. We must seek for conditions which stimulate creative powers, imagination and enthusiasm, and beware of checks on them as well as on the scope or direction of inquiry.

There is yet another point at which conditions of scientific work are affected, if not determined, by the nature of the society in which the man of science works. A totalitarian regime clearly is inconsistent with full freedom of scientific inquiry and ultimately fatal to the advance of knowledge, but other political systems may have their own effects through their influence on the various types of incentive—social as well as economic—which summon the scientific worker to give of his best. Dr. J. B. Conant made a wise point in his address to the American Philosophical Society's symposium when he referred to the importance here of the quality of the appeal to the brilliant and enterprising sons and daughters of the mass of our society. That appeal, he thinks, should be couched neither in utilitarian terms nor in those appropriate to the secluded retreat, but rather that in each area of the entire field of learning the activities under way must be manifestly relevant to the future of our civilization, not only to man's physical and social needs but also to his highest hopes and aspirations.

The relations of science to society and even to industry are in fact more complex than some of the more ardent protagonists of planning care to admit, and Dr. Conant's suggestion of relevance rather than utility as the touchstone to test the vitality and validity of a scholarly enterprise indicates a line of thought to be explored more fully. Again, the limitations of the scientific method as applied to social problems, the looseness with which the term is employed, to which Dr. Conant directs attention, equally merit consideration, as much as the greater emphasis on philosophy for which he calls. It is the

absence of an adequate philosophy and consequent failure to develop the capacity for making disciplined and well-informed judgments on all those matters of value which are involved in so many vital human decisions that has been responsible for the weakening of civilization and the growth of barbarism. From no point of view can we be satisfied any longer with a system of education that fails to develop that capacity. It must be one of the prime requirements in future of all our training institutions, both for teaching and research, and we should vigilantly watch to see that no subsequent organization impairs or retards that same capacity of judgment.

Dr. Conant has assuredly put his finger on the weak spots. It is not that high standards of performance as to the technical part of his task are not essential for the scholar whether man of science, mathematician, philosopher or historian. Equally essential, however, are integrity of purpose, a disciplined imagination, and the power of critical analysis of both the problem at hand and the investigator's own contribution. To provide such men and women who come into the court of public opinion with clean hands and a consecrated heart, and to maintain their integrity and consecration and critical and imaginative powers undimmed, should be a first objective of our research strategy. The institutions and organization which can succeed in this will never lack the flow of creative thought and fundamental discovery upon which the advancement of science and of civilization both depend.

There are therefore at least two problems involved here. First re-examination of our whole educational system, not merely at the university level, with respect to the provision of an adequately trained and broadly educated personnel to enter the field of scientific research, and the balancing of the immense needs for technical and scientific training by competent education in the liberal arts and humane studies. The emphasis must be on the balance, for the second problem is that of securing competent direction of research. That is no less vital. It forms the link between the two things which, as the Goodenough Report on Medical Schools points out, a community that wishes to promote research must do. "First and foremost, it must find and train the men who have the ability and impulse for scientific inquiry. Secondly, it must create the most favourable conditions for their work and give them the tools they need."

It may well be that the most valuable result of the establishment of more senior fellowships in science on the lines of the scheme recently initiated by the directors of Imperial Chemical Industries, Ltd., will be the contribution it makes to throwing up men of the requisite outlook and calibre for the direction of research. The wise insistence on some combination of teaching with research under conditions where, as Bruce Truscott notes, compared with industry, the fellows can be sure of time and tranquillity of spirit, may stimulate not merely fruitful research itself but also clear and creative thought about the compartmentalism of science, its effect on training or restraint on effective research. From such thought alone can come the competence and confidence to move surely across boundaries and to handle wisely the attack on the unknown, whether it be in industry or elsewhere, with its calls for team-work as well as initiative and individuality.

The Goodenough Report in its brief reference to research well stresses, in quoting from the evidence submitted by Sir Thomas Lewis, the importance of these last factors. Organization, in fact, must be secondary to the selection of personnel. Unless we can secure an adequate supply of men of the right gifts no organization will ensure the prosecution of effective research, and the essential preoccupation of wise administration is, as Alan Gregg observes, to create and foster the circumstances, the human relationships, in which gifted men will be most productive and prodigal of their gifts. In particular, he points to two dangers which our strategy must frankly recognize and provide against: first, the tendency to waste research ability by diverting it into other channels by the demands of administration and teaching; and secondly, the tendency for the endowment of research to deprive the investigator of his primary right of choosing a subject to be studied, of framing a hypothesis to be tested, of planning and performing some crucial experiment.

It may be noted in passing that Mr. Gregg looks to senior fellowships for research of much the same type as those contemplated in the scheme of Lord McGowan and his fellow directors to meet this need, though he appears to have a slightly higher standard of status and emolument immediately in mind. The basic strategy is clearly the same, and the same close resemblance in the conclusions reached by progressive minds in Great Britain and in the United States may be discerned in the broad objectives of some of the programmes of research. The differences in content are frequently rather in points of detail than in scope, though the emphasis on particular aspects of the programme must obviously vary.

A noteworthy example may be found in the field of agriculture. The research programme recently adumbrated by the Parliamentary and Scientific Committee in its report, "A Scientific Policy for Agriculture", has features in common with the more detailed programme outlined by Dr. E. C. Auchter in his address last autumn to the American Association of Land-grant Colleges and Universities (*Science*, 99, 169, 190; 1944). Whereas the former does no more than indicate that an expenditure of at least three million pounds on agricultural research is required, with the completion of British soil and geological surveys, and intensive and large-scale research into the complex part played by organic matter in our soil, it recognizes that nutrition must play an important part in determining the trend of agricultural research, and like Dr. Auchter again, that agricultural research is linked up with and affected by fundamental research in other fields.

This point, of which the Parliamentary and Scientific Committee has already shown itself

aware in its earlier report on coal utilization, is specially well brought out by Dr. Auchter. In addition to nutrition, he points to the value for plant and animal production of a detailed systematic world geography of soils, climatic conditions, varieties of plants and methods of plant and animal production, to the need for research on new immunizing agents, into engineering and electrical and mechanical problems in agriculture and the use of agricultural products, into the utilization of crop residues and to basic research to extend our knowledge of such substances as starch, proteins, lignin, hemicellulose, enzymes, hormones and vitamins. If for a moment we have passed from the consideration of broad objectives to that of detail. it is to demonstrate more conclusively first, the validity of Dr. Conant's criteria of relevance in determining the broad objectives, and secondly, the way in which programmes are interlocked, and work in furtherance of the broad objectives in one field may involve work in quite another field.

Strategical requirements, whether from the point of view of applied or fundamental research, may well thus require us to reconsider the compartmentalism of science and to facilitate both team-work between workers in one or more sciences and the abrogation of the impediments such compartments offer to effective research. Beyond this the broad strategy of research would seem to involve first the provision, on this basis of relevance to social needs, for the organized study of particular and urgent problems, both in the development of natural resources, as of fuel and power supply and agriculture and their effective utilization in the service of the community, and of nutrition and health, including the treatment or control and the prevention of disease. Such organized study must include adequate provision not merely for many lines of industrial research but also for systematic fundamental research, planned at least so as to assist the advance of science on an even front by filling in the gaps left by individual initiative and with special regard to the borderlines of the sciences at once so apt to be neglected and so richly productive when cultivated. Again the conception of relevance must include relevancy to the needs of the Colonial peoples also, and it is worth noting in passing that the first annual report of the Colonial Research Committee contains an admirable discussion of strategy in relation to the organization of Colonial research.

There are yet two further aspects of such broad strategy which should be noted. First, provision for the organized study of particular and urgent problems the social relevance of which is immediately apparent leads us almost imperceptibly, through the consideration of such questions as transport, the utilization of the land, water supply, the planning of town and country and the location of industry, to the study of a whole range of problems in the social sciences the immediate relevance of which may be less apparent. Without adequate attention to social biology and the biological factors in human relations, to population changes and vital statistics, to psychology, and allied subjects, we shall be without the basic knowledge we require for the evolution of a new social order or for the establishment of better human relations either at the industrial or at the international level, as well as without the effective technique for handling and improving such relations. As Roy Glenday points out in a recent book, "The Future of Economic Society", we need to know much more about the principles and rules which will govern the social and economic organization of the groups of human beings of which the new world order will be composed. Even more emphatically, Dr. J. T. MacCurdy in discussing, in "The Structure of Morale", this problem of organization indicates how far we have to go when he says that man can expect to fabricate a social organization that will be adaptable only when he has developed a liaison system comparable in its intricacy with the individual human brain.

The suggestions for research which Dr. MacCurdy has made in this connexion should be considered in framing our broad programme of research, and they bear closely on the second aspect of strategy which remains to be considered. If there were any scientific workers who imagined that research strategy could be considered entirely without reference to politics, they should have been disillusioned by the reception which has been given to the report of the Parliamentary and Scientific Committee on "A Scientific Policy for Agriculture". The suggestion that policy should not be shaped primarily or excessively by sectional interests but should be based on the application of scientific principles has been represented as an attempt to dictate policy by reference to such principles alone.

The attempt to formulate and to apply an adequate strategy of research is clearly liable to like misrepresentation, for such strategy can only be put into operation when it receives the necessary political support. It must be therefore a primary responsibility of scientific workers in endeavouring to think out such a strategy to undertake simultaneously the corresponding and no less essential task of explaining and interpreting that strategy to their fellow citizens. At this point no less than in the application of scientific and industrial research in industry educational work has to be undertaken. That is a task of co-operation as well as education. As Mr. Glenday observes: "Before scientists can claim the right to plan a new world order, they must first plan science itself by organizing its various departments to the point of making possible effective co-operation between them". Such endowments as Lord Kemsley's travelling fellowships, the fellowships in science offered by Imperial Chemical Industries, Ltd., and the trust fund for economic and financial research established by the Bank of England should be taken by scientific workers as a challenge both to fundamental thinking on the strategy of research and to full and resolute co-operation alike in the exposition and interpretation of science and in setting their house in full order. Their training has developed in them the critical and unprejudiced approach to novel problems in their particular fields; they must now apply this faculty in a wider field.

# THE HUMAN FOOT

**Structure and Function as seen in the Foot**
By Prof. Frederic Wood Jones. Pp. iv+329. (London: Baillière, Tindall and Cox, 1944.) 25s.

PROF. WOOD JONES is a distinguished member of a long line of British anatomists who, from the time of John Hunter, have refused to limit their activities to the dissecting room and to circumscribe their work within the confines dictated by the supposed immediate requirements of surgery. The line includes Owen, Turner, Humphry, Flower, Cunningham, Elliot Smith and, fortunately still with us, Sir Arthur Keith, and Profs. Arthur Robinson, T. H. Bryce and J. T. Wilson. All these professed human anatomy but all were also excellent comparative anatomists, neurologists or embryologists, and the influence of their wide interests on the advance of anatomical knowledge is not adequately realized. Prof. Wood Jones, in continuing this great tradition, has made significant contributions to mammalian comparative anatomy and, in his publications, he has shown great skill in presenting the detail of human anatomy against a background of mammalian structure which enables one to separate most reveal-ingly those human characteristics that can be regarded as primitive from those that are specialized.

In the book under review Prof. Wood Jones gives an excellent account of the structure of the human foot. The account is none the worse for being, from time to time, iconoclastic and even provocative. It takes for granted an introductory knowledge of human anatomy and will be more readily followed if the reader has already studied, as he should have done, the author's "Principles of Anatomy as seen in the Hand", for the two books are complementary. Doubtless every anatomist could find points of detail with which he would not agree, but, in general, the descriptions are clear, succinct and, often, illuminating. The figures, which have been drawn by the author himself, are most helpful in clarifying the descriptions and they possess the added merit of a quite engaging charm. Omissions, too, will be noted by every anatomist, in accordance with individual prejudice. Thus, in the reviewer's opinion, some reference to Wheeler Haines' work on sesamoids and secondary centres of ossification would have been useful, and the absence of reference to the architecture of the bones, and more particularly to Weidenreich's study on the structure of the calcaneum, is surprising.

The interest of the author in comparative anatomy and in the problems of human phylogeny is revealed in every chapter; but he is careful to warn most emphatically against too much reliance on tags of morphology for assumptions, by analogy, as to function. The case against the 'gorilloid' theory of the derivation of the human foot is convincingly presented, though it is, perhaps, too much taken for granted that this theory, in its extreme form, is widely held. Most anatomists are of the opinion that the early hominoid stock was not derived from an anthropoid ape of the degree of specialization of the extant great apes, and most also believe that the separation of the hominoid from the anthropoid stock occurred at an earlier geological stage than has sometimes been held. But, equally, most workers on primate phylogeny cannot overlook the innumerable structural resemblances between the great apes and man. These resemblances are all-pervading. They extend, as Heuser's account of the ten-day chimpanzee 'ovum' shows, to the very early stages of development, and it would be unfortunate if Prof. Wood Jones's demonstration of the unlikelihood of a 'gorilloid' stage in the phylogeny of the human foot was taken to indicate a more remote relationship between man and the anthropoid apes than, in fact, a survey of all the relevant facts appears to warrant. Notwithstanding this caveat, however, Prof. Wood Jones has made his primary phylogenetic point most persuasively, though some of the argument used in establishing it ignores the significance of allometric, or heteroauxetic, growth in producing differences of proportions of bones in quite closely related animals. Those gene changes concerned in the causation of, say, achondroplasia can alter limb proportions most strikingly without leading to the opinion that the resulting dwarfs represent a new species.

On the functional side Prof. Wood Jones's analysis is again often illuminating. This holds especially for the descriptions of muscular activity and the accounts of movements at the different joints of the foot. His insistence on the freedom of movement at the talo-calcaneal joint is noteworthy, since, in spite of the ease with which the facts can be established, the text-book accounts of this joint are unsatisfactory. The account of the arches of the feet emphasizes the importance of the ligaments in the maintenance of the longitudinal bow, as he prefers to call it. Absence of the anterior metatarsal arch is accepted, but there is no reference in this chapter to the views of Morton, Bankart, Lake or Bruce and Walmsley. A little more emphasis on the clinical importance of proper foot function might justifiably have been introduced, especially as some of the opinions expressed have implications for that part of orthopædics which deserves better than to be called, as it is coming to be called in the United States, podiatry.

"Structure and Function" appears in the title of Prof. Wood Jones's book, and the descriptions of isolated structures and functions throughout it are excellent. There is, however, for the reviewer, no satisfactory attempt at integration of the two. That structure is adapted to function is taken for granted, and little stress is laid on structure which may conceivably be non-adaptive. Further, having taken the structural adaptation to function for granted, there is no reference to the importance of the sieve of natural selection in the establishment of the adaptation. Prof. Wood Jones is an unblushing supporter of the theory of the transmission of acquired characters, and inherent in his whole approach to the study of structure there is the restricted teleology of the end in view. The reactions of readers to this approach will doubtless be conditioned by their individual philosophical attitudes. At least one of them, who has, he believes, followed the arguments sympathetically, remains unconvinced by Prof. Wood Jones's examples, and will adhere to the orthodoxy that there is no good evidence for accepting the doctrine of the transmission to offspring of modifications produced in response to functional requirements. Prof. Wood Jones writes: "Every simile that is called upon to explain the ordering and working of structures and organs in the living body is derived from the unliving world of mechanistic physical science. No real understanding of the longitudinal arch of the foot will ever be come by in attempting to assess its character in terms of the triumphs of the architect or the engineer". Ends, not antecedents, satisfy him as they have satisfied many others; most biologists,

however, will prefer Boyle's "industrious indagation of efficients" and will find their apologia in the first chapter of Sir D'Arcy Thompson's "Growth and Form". J. D. Boyd.

# RECENT WORK ON MAGNETOCHEMISTRY

Magnetochemistry

By Prof. Pierce W. Selwood. Pp. ix+287. (New York: Interscience Publishers, Inc.; London: Imperia Book Co., 1943.) 5 dollars.

IN hybrid terms for investigations involving the experimental examination or the theoretical consideration of particular physical properties of substances, the words 'chemical' or 'chemistry' are often used where they serve no useful delimiting or other purpose. The author of this book possibly feels the difficulty, and gives an explicit definition of magnetochemistry as "the application of magnetic susceptibilities and of closely related quantities to the solution of chemical problems": This, however, is not a severe limitation, for any problem of structure, whether atomic, molecular, or crystalline, which arises in the consideration of the experimental results, may be regarded as a chemical problem; and in fact the subject-matter of the book is virtually the entire range of results for susceptibilities, and their interpretation.

The author makes graceful acknowledgment to other books on the general field, and does not give detailed references to work prior to 1934. Since then to the end of 1942 he states that more than one thousand papers on magnetochemistry have appeared. The problem of selection seems to have been avoided by referring to all of them, for specific reference is made in the text to some twelve hundred papers indicated in footnotes. The book is thus in the main an extensive survey of the recent literature along lines similar to those followed in the "Annual Reports" of the Chemical Society. It would, therefore, scarcely meet the needs of those seeking an introductory or a general account of magnetochemistry; but to those who already have some familiarity with, and interest in, the subject such a survey can be of immense service, particularly at the present time.

The author's own practical experience is evident in the first chapter, where the most useful methods for determining susceptibilities are briefly but clearly described. Among the general explanatory remarks, however, there are a number of loose or definitely incorrect statements. It is stated, for example, that substances are called dia- or para-magnetic according to whether the "intensity of the field" in the substances is smaller or greater than that in the surrounding space (p. 1); that for ferromagnetics the intensity of magnetization becomes proportional to the field "only at high fields, when the specimen is said to be saturated" (p. 17); that specific magnetization is "given by the slope of the susceptibility plotted against reciprocal field strength" (p. 18). Slips of this kind are fortunately not typical of the whole book.

The main subject-matter is grouped in seven chapters each covering a particular class of substance. The grouping is not explicitly discussed, but from a magnetochemical point of view it is logical and convenient. The chapters deal with atomic and molecular diamagnetism, atomic and molecular paramagnetism, complex compounds, metallic dia- and para-magnetism, and ferromagnetism. A final chapter deals with miscellaneous topics under the general heading of applied magnetometric analysis.

Atomic magnetism is, as usual, taken as a general term covering the magnetism of ionic crystals, in connexion with which experimental work and the quantitative theoretical treatment earliest reached a fairly advanced stage. The survey is mainly of additional data accumulated during the last ten years. The author deliberately refrains from including tables of susceptibilities, on the ground that "Annual Tables" of such data are to be published; but it may be suggested that much of the information included in the continuous narrative could have been conveyed in more convenient form by means of suitably annotated tables. It is surprising to find how incomplete the experimental information still is on the compounds of transition elements other than those of the first and of the rare earth series.

The most valuable parts of the book are the chapters dealing with molecular paramagnetism and complex compounds, on which the experimental work in recent years has been very extensive. It may happen that the susceptibility is determined, with close approximation, by the number of unpaired electron spins in the molecules, the magnetic effect of any orbital moments being negligible; when this is so, and if no searching inquiry is attempted, the magnetic aspect of the problems is often fairly simple. Not so the chemical aspect; for very difficult problems of structure may arise in connexion with, for example, organic free radicals and biradicals, complexes such as those of chromium and manganese, and hæmoglobin and related compounds. Magnetic measurements are proving invaluable as a guide, and it is most useful to have a survey written with so thorough an appreciation of the chemical background.

To many physicists the magnetic properties of metals are now of outstanding interest, partly, perhaps, just because they are beyond the scope of the theory which is adequate for 'normal' dia- and paramagnetics. It is useful to have recent results collected together, but the theory of metallic magnetism is barely mentioned, and without it the significance of the susceptibility data is not brought out. Much the same remark applies to the material surveyed in the chapter on ferromagnetism, though here there is considerable specific value in the systematic survey of the results for the oxides and other ferromagnetic compounds of iron, and of the non-ferrous ferromagnetic compounds, which are often dismissed rather summarily.

The last chapter includes a description of a number of instruments used in metallurgical control, and a rather sketchy survey of magnetic work on the structure of alloys; it closes with some statements about the susceptibility of sea urchin eggs and sperm.

Those who write surveys of scientific literature undertake a thankless task. Omission of reference to some particular piece of work may give offence; completeness of reference, in reasonable space, is possible only at the sacrifice of other desirable qualities in a book. Over most of the field the references here seem all-inclusive, and as a comprehensive digest of the literature the book is beyond reproach. It might have been much more readable if the author had been less conscientious, and had not attempted to cover so wide a range. The book, however, will probably be used mainly for reference,

so that the paragraph which states merely that colloidal magnetite has been examined, and the remarks on sea urchin eggs, may fulfil a useful purpose. The author expresses the hope that the book may contribute, however infinitesimally, to the labours of those scientific men who are seeking to parry the blows of an enemy. It may not do that; but it certainly will perform a valuable service in one small region of endeavour in helping to bridge the devastating gap which is being made by the war years.

E. C. STONER.

## SURVEYING FOR STUDENTS

### Higher Surveying

By Dr. Arthur Lovat Higgins. Pp. viii+463. (London: Macmillan and Co., Ltd., 1944.) 25*s.* net.

THAT Dr. A. L. Higgins is an enthusiast where the subject of surveying is concerned will be evident to readers of his latest book entitled "Higher Surveying". It is written on somewhat unorthodox lines, each section consisting of a number of "Articles" followed by a selection of examples.

Though ostensibly written for students, the book should have a much wider appeal. The articles are well written, and many of them are concise critical essays on appropriate surveying topics: they include many historical references and discuss modern developments. It may be that these scholarly outlines will sometimes be more appreciated by those who already have a good knowledge of surveying than by the student whose horizon is less wide. Even if not fully understood by the student, however, they will give him a broad view of the subject, into which later knowledge can be fitted.

The impression is given that Dr. Higgins had a great deal of trouble in deciding the scope of the book, and in fixing its title. In the first place, he had so much material that he decided to jettison much that was of a more elementary character, and also some details of field technique which the student might be expected to learn in the field. It probably seemed too drastic to carry out this policy rigidly, and opportunities have been taken in the text and examples to incorporate much that is not strictly 'higher surveying', but which completes and rounds off the treatment of other subject matter. Even with these omissions the author's troubles were not ended. He was anxious to include a considerable number of worked examples taken from university examination papers, and also others for the student to solve. Consequently, with the space at his disposal, he had either to omit subject matter he was anxious to include, or deal with it in a less detailed manner than he would have wished. In some cases the examples have been used, not to illustrate the text, but to supplement or even as a substitute for it. In other cases the text is somewhat too concise and condensed for easy reading. The reviewer considers that Dr. Higgins has overcome his difficulties very successfully, and the book cannot fail to be of great value to its readers.

The six main sections of the book deal respectively with (1) instruments, (2) engineering surveys, (3) photogrammetry, (4) field astronomy, (5) geodetical surveys and (6) errors in surveying.

These sub-titles sufficiently define the scope of the book. It is from the section on engineering surveys that much of the elementary work on chain surveying, traversing, levelling, plane-tabling, etc., has been omitted. Section 3 deals with both ground and aerial surveying, and is necessarily selective. The last section, of about sixty pages, dealing with errors of surveying, contains a mass of information, the theoretical work being rather too concisely expressed, but with the applications fully explained by means of numerical examples.

Finally, it may be said that the production is excellent, and the publishers are to be congratulated on presenting so well, in war-time, this most useful and attractive text-book.

W. N. THOMAS.

## THE STUDY OF FINE PARTICLES

### Determination of Particle Size in Sub-Sieve Range

A Report of Discussions. Pp. 69. (London: British Colliery Owners' Research Association and the British Coal Utilisation Research Association, 1944.)

THE measurement of fine particles is a subject of increasing importance in many industrial processes and in the study of natural phenomena concerning soils and dusts. It is now realized that the influence of very fine particles is so predominant that in many researches measurements would be desirable to a lower limit of one micron in diameter, though it is not often that this degree of accuracy can be attained. The above report contains an account of the activities of two research associations having the object of improving particle size measurements, and they may be complimented on the broad way in which the problem has been treated.

The volume reports two informal conferences held to discuss the subject, with an introductory paper by Drs. Skinner and Boas-Traube and Messrs. Brown and Hawksley. This paper summarizes recent developments in the measurement of fine particles, dealing with microscopical measurement, the dispersion of various powders in liquids, and in considerable detail with the measurement of size distribution by determining the rate of change in optical density of a dilute suspension of the powder in a liquid. This latter method is now being extensively used both for research purposes and for the rapid checking of industrial products as a routine procedure. The report of the second conference expresses the views of research workers from various laboratories of the Department of Scientific and Industrial Research and a wide range of industrial organizations.

From this discussion it is apparent that the problem needing most urgent research is that of effectively dispersing a powder in a liquid, since this procedure is involved in almost all methods of sub-sieve particle-size determination. A large number of peptizing agents have been suggested for various powdered substances, but no general theory has yet been developed that would obviate the present method of proceeding by trial and error. Many processes and designs of apparatus are now available for measuring sub-sieve particles which are satisfactory for comparing the fineness of various powders, but serious discrepancies are shown to exist when the same powder is tested in different designs of apparatus. Thus it is evident that further research is necessary on many details before the absolute size distribution of the finest particles can be determined; but the report is a valuable guide to those engaged on particle-size measurement regarding the choice and most effective way of using such apparatus as is available.

H. HEYWOOD.

## Solvents

By Dr. Thos. H. Durrans. (Monographs on Applied Chemistry, Vol. 4.) Fifth edition, revised and enlarged. Pp. xii+202. (London: Chapman and Hall, Ltd., 1944.) 17*s*. 6*d*. net.

WHEN this book was first published in 1930 it was not generally appreciated how useful organic solvents were and how wide their application could be. Since then they have become of prime importance, and their manufacture is an important section of the fine chemical industry. This little book has undoubtedly contributed to their use; it gives just the required amount of information in detail about each of them, as well as a general section about their behaviour in general. Organic solvents have adverse as well as useful properties: they are toxic and have a considerable fire risk. Workers with them risk chronic poisoning, so that guidance in their use is required: the book contains the necessary information including the relevant data regarding critical concentrations. Similar data are given for the explosive limits of the various substances.

There are now so many of these solvents, most of them sold under trade names, that it is hard to know what they are. The appendix giving the trade names and probable composition is therefore especially valuable: it occupies eight pages with some four hundred entries.

A second appendix shows in tabular form the power of the solvents to dissolve twenty-five named substances mostly used by the plastics industry. The work is a mine of information, and its frequent revision enables it to be kept up to date and accurate.

There is no indication of any particular new solvents, though such are continually being added to the list. Dr. Durrans is to be congratulated on his efforts, which are greatly appreciated by all users of solvents.

## Aeroplane Flight

By H. F. Browne. Pp. 167. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1944.) 7*s*. 6*d*. net.

THERE is already a flood of books on the elements of aerodynamics purporting to be written in non-technical language for the beginner. Many of these fail to fulfil their authors' intentions simply because the explanations assume a knowledge of mechanics and physics not to be expected of the non-technical reader. Mr. Browne does not commit this mistake. He explains the principles of mechanics as he meets them in very simple language, using homely everyday examples, illustrated by unique sketches of his own preparation. These diagrams are perhaps the most outstanding feature of the book, and they have been made to illustrate the text in a way that photographs or sketches of actual aircraft parts could never equal.

The subject is discussed in chapters each dealing with some part of the theory of flight such as lift, stalling, drag, thrust, control, stability and performance. There is also a discussion on the mathematical units involved, leading up to a chapter on wind tunnels and the interpretation of their results. The explanations of some of the more complex ideas are extremely good. The mechanics of the airscrew, the gyroscope and gyroscopic action, and the meaning of "Reynolds Number" in aerodynamic experimental work, are examples of the way in which the author has succeeded in putting the technical facts into language that is both simple and mathematically true.

While this book is essentially for beginners, its method of presentation of the subject might well be studied by many teachers.

## The Annual Register

A Review of Public Events at Home and Abroad for the Year 1943. (New Series.) Edited by Dr. M. Epstein. Pp. xii+176. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1944.) 42*s*. net.

THE new issue of this annual record follows the usual arrangement. The greater part is devoted to a factual and objective story of world history divided into national sections, half of which treat of Great Britain and the Dominions; the British Colonies have no separate section. The record is chronological, which puts the social history into perspective with the history of the War, and so gives an admirable sketch of human interests in the year. Under the headings of various enemy or enemy-occupied countries, there is much social history, some of which failed to receive adequate notice in the restricted newspapers of to-day.

The second half of the book has the usual surveys of literature, with reviews of some outstanding books, art, music, drama, science, law and finance. The review of scientific achievements is comprehensive though very condensed and perhaps less readable than some of the other sections. Then follows a record of events, obituary notices and a long and detailed index.

In addition, certain public documents printed in full include the Anglo-Chinese Treaty concerning Extra-Territorial Rights. In spite of the crowded events of the year, the editor has succeeded in producing a balanced volume of the same size as previous issues.

## Elements of Radio

By Abraham Marcus and William Marcus. Prepared under the editorship of Ralph E. Horton. Complete edition. Pp. xiii+699. (London: George Allen and Unwin, Ltd., 1943.) 27*s*. 6*d*. net.

THIS book, printed in the United States, is in the nature of an elementary course of instruction in radio technique on very practical lines. The authors state that as a result of many years experience of teaching this subject, they consider it a mistake to require the student to learn a mass of laws and principles of electricity before teaching him radio. The first half of the book deals with the radio receiver, starting with the crystal detector and leading up through valve detectors and amplifiers to the superheterodyne type of receiver. The second half of the book is slightly more advanced, and deals first with the phenomena of direct and alternating current electricity and their applications; and then with the essential characteristics of radio transmitters and auxiliary equipment.

The style throughout is very elementary, with very clear diagrams, and includes a series of questions, problems and practical exercises and demonstrations, all of which are probably very suited to a particular type of instruction designed for a short-period (one year or less) course. Only the simplest of formulæ are included, such as for the calculation of circuit constants; and the technical material is clearly and accurately presented.

# MEANING AND SCOPE OF SOCIAL ANTHROPOLOGY

By PROF. A. R. RADCLIFFE-BROWN
University of Oxford

THE name 'social anthropology' came into use some sixty years ago to distinguish the subject from ethnology. The avowed aim has always been to apply the inductive method of the natural sciences to the study of human society, its institutions and its evolution. But it is only gradually that we can learn how to apply the inductive method in a new field. The history of chemistry from the time of Bacon to Lavoisier illustrates this. So social anthropology is not now what it was in 1890. At that time theoretical discussions in social anthropology were largely concerned with speculations about origins (of religion, of totemism, of exogamy, etc.). There are still some social anthropologists who remain faithful to the ideas and methods of 1890. But the work now being done in the subject consists largely of experimental studies, combining observation and analysis, of particular social systems, intended to provide material for the systematic comparison of systems of different types and to test existing hypothetical conceptions. Anyone who wants to know what social anthropology is doing at the present day should read the admirable work of Arensberg and Kimball on "Family and Community in Ireland".

One of the most completely organized departments of anthropology is that of the University of Chicago. The subject is divided into five fields: physical anthropology, archæology, ethnology, linguistics and social anthropology. Students, who must already have the degree of B.A. before entering the department, are required to devote a period of study to all five subjects and pass a comprehensive examination in all of them. Thereafter the student specializes in one of the fields for his degree of Ph.D. A brilliant student can complete this work in four years, but many take longer.

We may consider this combination of subjects from the point of view of each one of them in turn. Physical anthropology proper, as distinct from human biology, is the study of variation in the human family (the Hominidæ) and of human evolution. It includes, therefore, not only the study of existing varieties of *Homo sapiens*, but also human and primate palæontology. A student who aims at being a competent physical anthropologist must first obtain a thorough grounding in biology, comparative morphology (particularly of the primates), human anatomy, histology, embryology and physiology. It seems desirable that he should have some acquaintance with archæology and ethnology. His own special work will in no way be helped by any study of linguistics or social anthropology.

Ethnology, as the name shows, is the study of 'peoples'. Peoples, or ethnic groups, differ from and resemble one another in racial character, in language and in culture. The ethnologist compares and classifies peoples on the bases of these similarities and differences, so that he has to deal with racial, linguistic and cultural classifications. Further, he seeks to discover by various methods something about migrations, interactions and developments of peoples in the past.

It is evident that the competent ethnologist should possess a sound knowledge of physical anthropology, linguistics and social anthropology. Ethnological literature is very heavily overloaded with uncritical speculations. A writer who talks glibly of brachycephaly and dolichocephaly but is completely ignorant of the complexities of structure of the skull will offer us an account of the movements and developments of races from the first appearance of man. One who is ignorant of linguistic science will affirm a connexion of two widely separated languages on the evidence of similarities of a few words selected from imperfect vocabularies. Or one who, by his lack of knowledge of social anthropology, is ignorant of the nature of institutions such as totemism or exogamous moieties, will affirm that these institutions all over the world must have been introduced by Egyptians looking for gold, pearls and cowrie shells.

Prehistoric archæology is really one kind of ethnology (palæo-ethnology), the study of the peoples of the prehistoric past who are known to us only from their remains—their dwelling sites, their bones, the implements they made and used. Since the archæologist recovers no traces of the languages or the social institutions of these vanished peoples he has no need, in the pursuance of his own special studies, for any knowledge of linguistics or social anthropology. On the other hand, he has to know something of geology and surveying. It would seem to be most desirable that ethnology and archæology should keep closely together. They are merely branches of a single study.

Linguistics, the systematic study of language in general, as distinguished from the study of particular languages or groups of languages, is regarded in the United States as one of the fields of anthropology. In England the subject, as a subject, has not yet received recognition except in the School of Oriental Studies, London. A student who intends to specialize in linguistics does not really need to know anything more about physical anthropology or prehistoric archæology than ought to be known by every educated person. But there are important connexions of linguistics with ethnology and social anthropology. For example, the ethnological problem of the Aryan people is a linguistic problem as well as an archæological, racial and cultural problem.

We come finally to social anthropology—the general theoretical study of social institutions—law, religion, political and economic organization, etc. Within his own field of study, the social anthropologist has no use for physical anthropology. If it should ever be proved that racial (that is, biologically inherited) characters influence social institutions or their development, then he would take due note of the fact.

Prehistoric archæology obviously makes no contribution to such branches of social anthropology as comparative religion, the comparative study of law or of kinship or of economic systems. It does not even provide very much help to the study of comparative technology as that is conducted in social anthropology, where what is sought is to determine the mutual interrelations between the system of techniques and the other parts of the total social system. Certainly a social anthropologist should be acquainted with the general results of prehistoric archæology, but the methods of the archæologist and the details of investigation are not his concern as a social anthropologist.

There is often a good deal of confusion about the relation of social anthropology to ethnology. To a certain extent, but only to a certain extent, they deal

with the same facts. But they deal with them in quite different ways. A typical problem of ethnology is how and when the ancestors of the American Indians entered the continent of America and how they developed the differences of racial character, language and culture which they exhibited when Europeans first came in contact with them. A typical problem of social anthropology is, "What is the nature of Law ?" An ethnologist and a social anthropologist might both study the same American Indian tribe, but one would be looking for facts relevant to his aim of placing the tribe within his general picture of the peoples of the continent; the other would be examining the way in which the tribe deals with infractions of custom in its bearing on a general theory of the nature and function of law.

Since both ethnology and social anthropology need field studies, there is an obvious economy of labour if a field worker can provide the material needed by the ethnologist and also that needed by the social anthropologist. In some field studies this has been done. But a field study in social anthropology needs more than description; it requires theoretical analysis. There are innumerable examples of ethnographic monographs which are admirable for the purposes of ethnology but are extremely unsatisfactory to the social anthropologist who might wish to make use of the data.

Ethnographical field studies are generally confined to the pre-literate peoples. In the last ten years, field studies by social anthropologists have been carried out on a town in Massachusetts, a town in Mississippi, a French Canadian community, County Clare in Ireland, villages in Japan and China. Such studies of communities in 'civilized' countries, carried out by trained investigators, will play an increasingly large part in the social anthropology of the future.

It is now possible to see that what holds the various branches of anthropology together is the central position of ethnology (with archæology) as the geographical, historical and classificatory study of races and peoples, past and present. It is for this reason that ethnology and anthropology are sometimes regarded as being one and the same. It is an interesting fact that the symposium (as it is now commonly called) on the future of anthropology at the centenary meeting of the Royal Anthropological Institute included discussions on physical anthropology, archæology, social anthropology and the study of material culture. There was no one to speak on the future of ethnology. Ethnology takes contributions from physical anthropology and linguistics, but gives little to them in return. Social anthropology as the study of evolution is in bad odour with some ethnologists at present, so that while they give little they also take little.

But what of the relations of the branches of anthropology to subjects that lie outside the field of anthropology ? Physical anthropology has its closest connexion with the biological sciences. There is a tendency to seek to absorb it into a wider study of human biology, which would, presumably, also include what is called social biology. The study of the Bantu languages or the languages of the American Indians is left to the anthropologist, but not the study of the Indo-European and Semitic languages. How (and why) draw a line between prehistoric archæology and the archæology of historic times ? But if no such line is drawn, archæology becomes continuous with history. Ethnology, or some part of it, is claimed as a subdivision of geography—ethnogeography. And where, at the present time, are we to put anthropogeography or human geography, in geography or in anthropology or in both ?

Ethnology deals with the history of peoples. But the rest of history is excluded from anthropology. Yet the closest connexion of social anthropology is with the history of institutions—economic history, the history of religion, of law, of political organization, of science, etc. But to the social anthropologist the history of Europe or of Christianity is of no more interest than the history of India or China, of Islam or Buddhism.

The writer of the article on "The Future of Anthropology" (see *Nature*, Nov. 20, 1943, p. 587), which surveyed the discussion at the centenary meeting of the Royal Anthropological Institute, asks, 'Who is to study the world-wide history and development of social institutions ?" The answer is, in the first place, the historians. The social anthropologist cannot examine for himself the original sources for the economic, political, legal and religious history of ancient Greece and Rome, India, China, Russia, Persia and Turkey. It is unusual for him to be thoroughly competent in even one of these fields. The social anthropologist, for the most part, has to take the facts about institutional history and development from the historians, though, of course, he has to exercise his judgment as to the reliability of a particular historian. What the social anthropologist does with this material is to use it to formulate his general hypotheses about law, religion, economic organization and so on. But these hypotheses need to be verified; and although some verification is possible by the comparison of different historical societies, the final test lies in actual (experimental) observation of existing social systems.

Political systems, economic systems, and systems of law are studied in social anthropology and also in economics, political science and jurisprudence. But there are very important differences of method. One of these, though by no means the most important, is that in the three studies mentioned attention is usually confined to certain types of society, whereas social anthropology has for its field all human societies and therefore tends to pay most attention to those which are neglected by the social sciences. It is true that at present there is no close connexion of the three social sciences with social anthropology, but this may be expected to develop as the last-named subject itself develops.

As anthropology is at present recognized, psychology lies outside. Yet social anthropology stands in a very close relation to psychology. To make the relationship clear it is necessary to distinguish between two kinds of psychology. Psychology is here taken to mean the study of the mental or psychic systems—if you will, the behaviour systems—of organisms. We may study the behaviour, the external manifestations of the psyche, of earthworms, rats or chimpanzees. General human psychology deals with the mental characteristics which are possessed by all human beings. Social anthropology deals with the characteristics of all human social systems. A social system consists of a certain set of social relations between certain human beings, exhibited to observation in their interactions with one another. It is obvious that one determining factor in the formation of human social systems is that basic human nature which it is the business of the general psychologist to study. Similarly, the nature of multicellular organisms is determined by the nature

of the living cell which it is the business of the cytologist, the biochemist and the biophysicist to study. The connexion between social anthropology and general psychology is just as close and of just the same kind as the relation between animal physiology and cytology.

There are also what may conveniently be called 'special psychologies'. These deal, not with the universal characteristics of human beings, with basic human nature, but with the special mental or behaviour characteristics of individuals, types, classes or groups. Psychiatry affords an example of a 'special psychology', as do attempts to define psychological 'types'—extrovert, introvert; schizophrenic, cyclothymic; pycnic, asthenic.

One of the 'special psychologies' consists of the study of the psychical characteristics (that is, characteristics of mind or behaviour) of the members of a defined social group, either a local community or a defined social class within a local community. When we study the 'psychology' of the French or the Germans or the people of the United States, we are dealing with those characteristics of mind or behaviour that result from 'conditioning' by a particular social system. Here the 'special' characteristics with which we are concerned are determined by the social system, while the social system itself is determined by the general characteristics of basic human nature.

It should be evident that there is a two-way connexion between social anthropology and psychology. Human societies are what they are because human beings are what they are. Similarly a human body is what it is because living cells are what they are. But why human beings belonging to a particular society or group exhibit certain characteristic modes of behaviour is because they have been 'conditioned', as the phrase is, by that society. Similarly the cells of a muscle act and react as they do because they are individual members of the muscle.

Prof. F. C. Bartlett (*Nature*, Dec. 18, 1943, p. 700) proposes drastic changes. He would give no place in anthropology to archæology, to linguistics (the general study of language), to ethnology (the geographical and historical study of races and peoples), or to social anthropology (as the comparative study of the forms of association found among human beings or as the study of social evolution). He would retain physical anthropology or anthropometry if it would abandon its present aim of studying evolution, variation and heredity in the human family and would devote itself to measuring physical characters that are correlated with differences of behaviour. He would also admit the study of material culture so long as it was limited to the study of the applications of natural knowledge and their influence on behaviour. He adds two other disciplines. One is the study of the effects of general environmental conditions on behaviour. The other is the study of "a group's psychological possessions, its traditions, beliefs, customs, ideals and of their repercussion upon social conduct". For Prof. Bartlett, anthropology should become a group of special psychologies dealing with the effects on behaviour of anatomical characters, environment, knowledge and the 'psychological possessions' of groups. Anthropologists need not fear, however, that Prof. Bartlett's drastic reforms will be carried out in the near future. Meanwhile, that 'special psychology' which is concerned with the way in which the behaviour of individuals is determined by the 'culture' of the society in which they live is already part of social anthropology. But to say that it should be the whole of it is to deny to social anthropology the right to that study of the nature of social systems and of their evolution which is the *raison d'être* of the science.

Applied social anthropology is not much more than twenty years old. It was developed in South Africa, England and Australia in connexion with problems of Colonial administration. About twelve years ago it secured, despite the opposition of some ethnologists, a footing in the United States, not only in the Indian Bureau but also in the Soil Conservation Bureau and in an investigation of factory efficiency carried out in a large factory under the direction of Prof. Elton Mayo of Harvard. Since the United States came into the War, large numbers of anthropologists have been called to Washington to carry out work which either is, or is supposed to be, applied anthropology.

There is a good deal of misunderstanding about applied anthropology, what it is, what it can do and what it cannot do, but that matter obviously cannot be discussed here. The recognition of applied social anthropology has certain very definite advantages and certain equally definite disadvantages. To mention only one of the latter, theoretical social anthropology is still in the formative stage. The demand on social anthropologists to spend too much of their time on practical problems would inevitably reduce the amount of work that can be given to the development of the theoretical side of the science. But without a sound basis in theory, applied anthropology must deteriorate and become not applied science but merely empirical practice.

What of the future? Social anthropology must claim a position of relative independence. (There are already chairs of social anthropology at Oxford and Cambridge.) This does not mean that it should sever its connexion with ethnology, with which it has always been associated; and its connexion with ethnology connects it indirectly with prehistoric archæology. It should maintain a close connexion with general linguistics, for language is a social institution. (At Oxford the only lectures on general linguistics have been those given in the Institute of Social Anthropology.) It could maintain a closer connexion with human biology than with the narrower subject of physical anthropology.

Outside the field of what is called anthropology, it must maintain or establish connexions with psychology, with history (more particularly economic history, the history of law, of political organization, of religion) and with economics, political science and jurisprudence. The history of culture, in the sense of the history of art, of music, of literature, ought not to be neglected in any complete social anthropology, nor, of course, technological history. In the training of a social anthropologist the first essential is a real understanding of the experimental method in scientific investigation, and this is best acquired by a thorough study of the history of science.

One part of social anthropology is the comparative study of economic systems. Surely there ought to be close connexion between this study and economics and economic history. Another part of social anthropology is the comparative study of legal systems, which demands a similar connexion with jurisprudence and the history of law; and so on with other parts of social anthropology. But what part of social anthropology would give a similar close connexion with the study of the somatic differences exhibited by the various races of mankind, or with the study of the date and the affinities of the Solutrean

or Capsian culture ? So long as ethnology continues to exist, it will provide a meeting-ground for archæologists, physical anthropologists, students of linguistics, and social anthropologists. Such a meeting-ground has been provided for a century by the Royal Anthropological Institute and will continue to be provided in the future. Any attempt to impose a more rigid artificial unity will be likely to produce exactly the opposite of the result at which it aims.

# GENETICS AND KARYOLOGY OF *DROSOPHILA SUBOBSCURA*

By Dr. U. PHILIP, J. M. RENDEL, H. SPURWAY and Prof. J. B. S. HALDANE, F.R.S.

MODERN genetical theory is largely based on the study of *Drosophila melanogaster*, which has proved a useful guide to the genetics of other organisms. But there has been a tendency to regard this species as a standard, and any deviations from its genetical behaviour as exceptions.

The genetical study of other species of Drosophila has not merely opened a promising field of comparative genetics; it has also demonstrated that most species show qualitatively novel features. Thus *D. virilis* has a number of labile genes, *D. miranda* has two *X*-chromosomes. In *D. ananassæ* the males are triploid for at least one gene. *D. pseudo-obscura* A, though apparently monotypic, is polymorphic for a number of intra-chromosomal gene orders, each with its characteristic geographical range; and *D. subobscura* has been found to be a structural heterozygote in both sexes. In general the comparison of species suggests that they differ at least as much in the arrangement and proportions of the gene material as with regard to genes themselves.

C. Gordon[1] began the genetical study of *Drosophila subobscura*, and we owe some of our stocks to him. The study was continued by Gordon, Spurway, and Street[2] and Christie[3], and we hope shortly to publish a series of papers on it. The species belongs to the *obscura* group of the subgenus Sophophora (Sturtevant[4]), and its diagnostic characters are given by Gordon (1936) according to Collin (unpublished). It appears to be a native British species, and seems to have a wide distribution in Europe. For in a letter sent just before the outbreak of war with Italy, Buzzati-Traverso and Pomini, of the University of Pavia, informed us that flies of our stocks had given hybrids with flies of a species found in Italy and Germany, on which they had made genetical and cytological studies. Its possible identity with Sokolov and Dubinin's[5] *D. obscura*-3 from the U.S.S.R., is discussed later. The flies can be caught fairly regularly under 'bleeding' elms and oaks. We know little of the several related British species, and have so far not attempted to study their systematics.

At mitotic metaphase there are five pairs of telomitic rod-shaped chromosomes, and one pair of 'dots'. The *X*- and *Y*-chromosomes, which are of equal length, are the longest pair of rods. They can also be distinguished from autosomes in that somatic pairing only occurs at their proximal ends.

The salivary gland nuclei contain one short and five long elements. The *Y*-chromosome is exceptional in including at least 15 euchromatic bands, which have homologues in the *X*. One of the autosomes carries a large swelling similar to the 'Balbiani Ring' of Chironomus. The long chromosomes contain a good deal of heterochromatin. In all other Drosophila species so far described, except *D. busckii*, the heterochromatin of the proximal ends of the chromosomes forms a large darkly staining chromocentre. In *D. subobscura* this heterochromatin consists of large pale granules, and there is no chromocentre (Emmens[6]).

The most interesting feature of the species is the polymorphism of the chromosomes, each of which presumably represents one element in Muller's[7] terminology. Almost all larvæ both from wild parents and laboratory cultures show inversion configurations in one to five of the long chromosomes; no translocations have been found. The different chromosomal orders fall into two groups.

(*a*) Both homozygous forms seem as viable and fertile as the heterozygote. In the four cases of this type so far studied, one order is by far the commoner, and may be taken as the standard, from which the other orders may be said to differ by one or more inversions.

(*b*) In three cases the heterozygote appears to be more viable and fertile than either homozygote. Most larvæ show salivary configurations proving that in at least two of the paired autosomes the homologues differ in respect of a compound inversion. These inversions are an included inversion covering the middle third of one autosome, two adjacent inversions covering three fifths of another, and a pair of overlapping inversions covering the distal quarter of a third autosome. Thus three of the autosomes have two (if not more) equally common isomeric orders. As they differ in respect of compound inversions, these should reduce crossing-over in heterozygotes very efficiently.

From a cross between two structural heterozygotes, or between a heterozygote and a homozygote, we should expect equal numbers of larvæ homozygous and heterozygous for a particular chromosome. In fact, there are significantly fewer homozygotes, though the nature of the selection against them is so far unknown. Its efficiency may be judged from the fact that a line which, before inbreeding, was heterozygous for the three inversions the heterozygosity of which is favoured by selection, is still heterozygous for all of them after fifteen generations of brother–sister mating. This would only be expected in one of 37,000 such lines in the absence of selection. Another similar stock was still heterozygous for all three after ten generations of brother–sister mating; after nineteen generations it was still heterozygous for one, and died out during the twenty-first. Stocks made cytologically homozygous for any two of the three orders tend to die out; however, we have one cytologically homozygous stock derived from a fertilized wild female; but this is extremely difficult to keep alive, though it can easily be crossed with our other stocks.

Thus the species resembles a permanent structural heterozygote such as many Oenothera species, though structural homozygotes are not quite inviable. Sokolov and Dubinin (loc. cit.) reported a similar structural heterozygosity in a species from Ukraine and Caucasia which they referred to as *Drosophila obscura*-3 without giving diagnostic characters. The detailed structure of the inversions seems to be different, and it will be of great interest to determine how close systematically their populations are to ours.

In some vertebrate species, such as mice, pure lines can easily be established. In others, brother–

sister mating leads to low viability or infertility, or else to lines which are not as homogeneous as expected. It is at least possible that in such cases cytological investigations may reveal a condition like that of *D. subobscura*. In any event, a small and rapidly breeding animal species in which inbreeding is harmful is a valuable object of genetical study.

In our present stocks forty-seven loci are marked by visible mutants, several of them by a series of allelomorphs, and forty-four of these loci have been assigned to linkage groups. On the $X$-chromosome we have fourteen loci, apart from lethals. Some of the sex-linked mutants, such as *yellow, cut, singed* and *bobbed* with a terminal locus and a normal allelomorph in the $Y$, are clearly homologous with those of other species. The homologies of the autosomal mutants are more doubtful. The most striking mutants without obvious homologues in other species are an incompletely recessive *white testis*, with no change in eye colour; *bulge*, a sex-linked recessive hypertrophy of the eyes, which may be folded without disarrangement of the facets; *short costal* vein, a sex-linked recessive abolishing one of the diagnostic characters of the genus; and *six-jointed*, an autosomal recessive giving an extra tarsal segment and rough eyes.

Many of the mutants were obtained by inbreeding the progeny of wild flies. Most of these are autosomal, but three are sex-linked. One of these, *withered* wing, found by Street and Gordon (unpublished), is interesting as being sex-limited, only appearing in homozygous females, and not in hemizygous males. It is therefore, like an autosomal recessive, largely shielded from natural selection. Though located near the proximal end of the $X$, it has no normal allelomorph in the $Y$-chromosome like *bobbed*. The other two, a lethal and a visible *dried wing*, are ordinary sex-linked recessives.

Since each long autosome will ultimately have three maps, one for each homozygous chromosome order, and one for the heterozygote, mapping is a slow process, but it is certain that the maps of all five long chromosomes will be longer than those of *D. melanogaster*. That of the $X$ is more than 150 units long, compared with 67 in *D. melanogaster*. The minimal estimates of the length of the long autosomes vary from 80 to 140 units, as compared with 47 to 55 units for the arms in *D. melanogaster*.

The total lengths of the genetical maps of different species of Drosophila are:

| | |
|---|---|
| *Drosophila virilis* | 788 (Chino)[8] |
| ,, *subobscura* | 570+ |
| ,, *pseudoobscura* A | 420 (Sturtevant and Tan)[9] |
| ,, *ananassæ* | 326 (Kikkawa)[10] |
| ,, *simulans* | 311 (Sturtevant)[11] |
| ,, *melanogaster* | 280 (Brehme)[12] |

Thus *melanogaster* is far from typical of the genus. Since the species do not differ markedly in the numbers of bands in the salivary chromosomes, the differences in map-length are probably due to differences in frequency of chiasma formation within homologous regions.

With such large map distances recombination values reach 50 per cent, and at least one, namely, $50 \cdot 82 \pm 0 \cdot 42$ per cent between *scarlet* and *interrupted* venation, the loci of which are more than 86 units apart, is perhaps above 50 per cent. We have also discovered negative interference in connexion with a large inversion in the $X$-chromosome. The presence of a cross-over in the region immediately proximal to this inversion, so far from diminishing the frequency of cross-overs in the region immediately distal to it, increases it about twenty-fold. Multiple crossing-over is, of course, much more frequent than in *D. melanogaster*, and we possess considerable data concerning it.

The effect of inversions on crossing-over is also quantitatively different from that in *D. melanogaster*. Thus a single inversion covering about a third of the $X$-chromosome and reducing the map-length by at least 80 units gave only one internal double cross-over in 8,000 flies. A single inversion covering about 15 per cent of this chromosome, and lying between loci giving 32 per cent of recombination, did not reduce this percentage. This and other facts suggest that chiasmata are localized.

'Non-disjunction' of the sex chromosomes, causing the production of female pronuclei with two or no $X$-chromosomes, occurs once in about 7,000 oogeneses. But, as in *D. pseudoobscura*, $XXY$ females do not give $XX$ pronuclei with an appreciably higher frequency than $XX$ females.

Meiosis can be observed in male imagines of this and other Drosophila species (Philip[13]). The three sex chromosomes in $XYY$ males form a loose trivalent and segregate at random. A male of slightly abnormal phenotype and two normal males were trisomic for one of the long autosomes, a condition which is lethal in *D. melanogaster*.

We have found four flies mosaic for sex-linked genes. One appeared to be wholly female and three gynandromorphs. One of these had two ovaries and two testes, all fairly well developed, but not normal. All the mosaics were 'fore and aft' rather than bilateral, suggesting a pattern of cleavage somewhat different from that of *D. melanogaster*. A sex-linked eye colour which was non-autonomous in two out of three mosaics is probably homologous with *vermilion* in other species.

Unlike all other Drosophila species so far tested, *D. subobscura* will not mate in the dark. Since visual stimuli are essential for mating, several mutant forms with abnormal eye colours, including *white*, which, though phototropic, do not respond to moving contours (Kalmus[14]) are male-sterile. The mutant *yellow*, as in other species, has a cuticle abnormally permeable to water and other substances (Kalmus[15]) and is at a disadvantage in dry environments. In *D. subobscura* it is also at a disadvantage as a male in mating. Normal females generally kick off yellow males which attempt to copulate with them. Yellow females show no preference. But it is possible by selection to obtain a stock in which normal females are comparatively tolerant of yellow males, though the normal body colour is still preferred. Thus we have demonstrated not only sexual selection of a more or less Darwinian type, but also the inheritance of degrees of preference in the female, such as Darwin postulated.

It will be seen that this native European species differs from all animals so far described (if Sokolov and Dubinin's form and our own are conspecific) in being normally a structural heterozygote in both sexes. It is also very favourable material not only for comparative genetics, but for the study of chromosomes with long map distances, of polysomy, of the genetics of behaviour, and many other topics. We hope after the War to compare the British and Continental races. It is also to be hoped that it will be studied in several British centres, in order to investigate whether it possesses geographical races or other adaptations to the different conditions in various parts of Britain.

We acknowledge gratefully a succession of grants from the Rockefeller Foundation which have made this work possible, and the hospitality of Rothamsted Experimental Station, which has allowed it to be continued after 1940.

# HEALTH EDUCATION IN YOUTH SERVICE*

THE Central Council for Health Education, which is recognized by the Government as one of its agencies for health education, has thought it timely to outline the part that it considers health education should play in the youth service of the future.

The general standard of health in the community at present falls so far short of possibilities that there is obviously much room for improvement; and one of the ways in which it can be improved is through health education. Clearly, education alone will not be sufficient—there is needed also an improvement in community conditions (particularly in regard to housing and nutrition). But it is only through education that people can be encouraged to make the best use of conditions as they exist and be made aware of the possibilities of improving them.

Ideally, health education should be a way of living and something that is almost insensibly absorbed in the home, the school, the youth organization and the work place, rather than a formal subject taught in set sessions at set times. It has, however, at least three important aspects—the imparting of knowledge, the inculcation of habits and the encouragement of attitudes. Knowledge will not of itself lead to better health; but it provides the intellectual background to habits already acquired and helps in the development of healthy attitudes. Many of the most important health habits must be inculcated long before the child is capable of assimilating the knowledge which justifies them; but their practice should be reinforced by theoretical understanding as soon as possible. Attitudes are influenced by home environment from the very earliest days, and in particular by the way in which habit-training is carried out, but they also require intellectual understanding for their fullest development. These three aspects of health education are thus closely inter-related.

Knowledge important in health education includes an understanding of the structure and functioning of the body and of the relationship between physical and mental health. Important also is an understanding of how the spread of disease occurs and how it can be prevented or reduced; a grasp of the social factors influencing the health and well-being of the community; and a knowledge of the personal and social measures necessary to enhance health and build up resistance to disease.

The bodily habits relevant to health education include those consisting essentially of the disciplining of natural functions (for example, eating and voiding) and those others (for example, personal cleanliness) which are essentially habits of civilization. Equally important are the habits of the mind and of behaviour in relation to society.

Among the important attitudes are those of normality towards the body and its functions, deviating neither towards prudish avoidance nor towards prurient curiosity; of regarding health not as a mere absence of disease, but rather as a positive state of joyous well-being; and of feeling a sense of responsibility for the state of personal, family and community health.

Since young people do not enter within the scope of the youth service at the age of fourteen without having been influenced very considerably by their earlier training, any consideration of the type of health education appropriate to the period of adolescence is dependent upon the making of certain assumptions about what will have been achieved before this period is reached. It seems reasonable to assume that by the time children reach the age of fourteen, they will have received in home, school and juvenile organizations, health education along the three lines of imparting of knowledge, inculcation of habits and encouragement of attitudes indicated above, up to levels appropriate to their stage of development. The definition of these levels is in the main a matter for parents and teachers, and those responsible for the youth service will need to continue to build from the levels already reached.

## Health Education in Youth Service

The special functions of health education in adolescence would appear to be the reinforcement and widening of earlier education, especially in those directions most affected by the maturing ideals, emotions, experiences and activities of this period. With the statutory raising of the school-leaving age, some of this education will be given in the last year or two at school, and with the establishment of young people's colleges, some will be given during part-time compulsory education. The extra year or two of compulsory education would be most usefully employed in giving systematic instruction in those aspects of health education for which the adolescent is now sufficiently mature—in intellectual and emotional development and in social experience and awareness. For many young people, this will be the last opportunity for systematic instruction, and full advantage should be taken of it.

A great deal, however, will still remain as the special function of voluntary instructional classes and youth organizations.

The whole spirit of health education in youth service should be such as to encourage the development in adolescents of an appreciation of the possibilities of reaching a high standard of personal and community health and the growth of a sense of individual responsibility for reaching this standard. Certainly importance should be attached to the measures which are required from the State, the local authorities, etc.; but it needs emphasizing that increasing social provision should be accompanied by greater individual effort.

Adolescents particularly need help in meeting the peculiar problems of the period through which they

* Memorandum by the Central Council for Health Education.

are passing: in physical problems such as the coping with the bodily changes of adolescence; emotional problems such as those arising from the development of sexual interests and urges; and social problems such as those of the relations between the young people and their parents, between young men and young women, and between the individual and society.

The age-range covered by youth service is one in which young people are very interested in the development of physical fitness, strength, agility and grace; and any plans for health education should take full advantage of this interest. The keen desire to make oneself attractive to other people provides a very valuable opportunity for education in the care of the body generally and perhaps particularly in the attainment of grace and poise and in the care of the hair and complexion.

The period of adolescence is also one in which it is essential to give some training for approaching maturity. Examples of such training are marriage preparation, parentcraft, home economics, and instruction in the measures needed for the maintenance in full health of the individual, the family and the community.

It is clear that in most youth organizations very little will be possible in the way of systematic courses of instruction. Young people in their leisure hours wish for recreation, and lectures should be arranged mainly in response to demands made by the members themselves. The skilful teacher will be able to stimulate such demands—often as a result of informal discussions which make clear the need for further information on specific topics—and lectures which have been requested by the members are likely to be given much more attention than would have been the case had they been forced on the members by the leader.

But while it is true that the atmosphere and practice of the educational system will be a vital part of health education throughout, this is pre-eminently true of the youth organizations. The whole routine of the club—activities, toilet arrangements, concern for the cleanliness of premises and equipment, insistence that habits acquired in the organization are for everyday use and not 'for club night only', personal relationships between leaders and members and between one member and another—is of the utmost importance. Thus the encouragement of camping, rambling, youth hostels, etc., as well as the more formal type of physical recreation, is an essential part of health education.

The extent to which health education will be carried out in youth organizations will depend largely upon the degree to which the leaders are themselves educated, able to colour the whole life of their organization, and able and ready to stimulate and respond to demands for information. In addition, therefore, to those qualities of personality which are essential to any successful youth work, all leaders should be alive to the need for and the possibilities of health education, should themselves have a positive attitude to health and should have that necessary minimum of basic factual knowledge which will enable them to plan their programmes in the best way.

Moreover, each club or group of clubs should have at least one leader specially qualified in health education. This person might in many cases be the physical recreation instructor, in other cases the instructor in first aid and home nursing or allied subjects.

Ideally, too, each club would have a medical adviser—who would be available to advise the youth leaders and the young people upon matters within his province. It must be recognized, however, that this ideal will not be attained for a long time ahead, and it is therefore all the more important that meanwhile there should be a corps of fairly highly trained youth leaders (each of whom might serve a group of clubs) who, while naturally not attempting to carry out the work of a medical practitioner, would nevertheless be able to give the organizations covered by them skilled help and advice on the principles of healthy living. The Central Council for Health Education is able to give local authorities help in training youth leaders to carry out this work.

No amount of training will make good leaders out of poor material; but native abilities and aptitudes may be reinforced by courses of instruction. In the organization of such courses the Central Council for Health Education again can give considerable help, and indeed, regards the training of youth leaders as one of its most important tasks. It has already held many such courses and is developing co-operation with the Central Council of Physical Recreation so that theory and practice may march together.

In this connexion, it is worth considering the institution of a certificate in health education along lines somewhat similar to that in physical recreation, awarded at present by the Central Council of Physical Recreation. Youth leaders, like other students, are the more likely to give serious study to a matter when they are working for a test, and have a natural desire for some documentary evidence of the standard they have attained. The Central Council for Health Education hopes to discuss with the Board of Education and its Youth Advisory Council the desirability of such a certificate and the terms upon which it might be awarded to persons judged suitable from other points of view.

While it is true that the best youth leaders can do excellent work even in a very poor environment, it is equally true that a general high standard of achievement depends upon the availability of adequate accommodation and equipment. Club premises which, with proper cloakroom, lavatory and toilet accommodation, will reinforce, not contradict, health teaching; physical recreation apparatus, playing fields, camping sites, swimming pool, youth hostels—these are the basic material requirements. There is also particular need for a permanent residential school, with attached model club, in which, throughout the year, youth leaders from all parts of the country may gather for training and refresher courses, of which the theory and practice of health education should form an important part.

## THE PHILOSOPHY OF RESEARCH

THE American Philosophical Society arranged a symposium on the "Organisation, Direction and Support of Research" for its autumn meeting, held during November 19–20, 1943, and the papers presented have now been published (*Proc. Amer. Phil. Soc.*, 87, No. 4, January 29, 1944). Together they constitute a notable contribution to the philosophy of research, dealing on the whole with strategy rather than with tactics, and though concerned primarily with American conditions, they are highly relevant to the present discussions in Great Britain on the

organization of research, the functions of the universities, the relations between teaching and research and like problems.

The first paper, Dr. J. B. Conant's Franklin Medal Lecture on "The Advancement of Learning in the United States in the Post-war World", well illustrates the general validity of the symposium. Free inquiry, he points out, is the necessary condition for the advancement of learning in any age, but while welcoming the debate between the schools of Bernal and Polanyi on the planning of science, Dr. Conant urges that relevance, not utility, should be the touchstone: in each area of the entire field of learning, the activities under way must be manifestly relevant to the future of our civilization. Following the argument of Francis Bacon, he reminds us that we must not mistake the mere acquisition of information for an advance in knowledge, and strikes a note of caution about our understanding of the scientific method and its limitations which recurs frequently in the symposium. Only in situations where value judgments can be eliminated from the frame of reference are methods comparable to those used in the advancement of knowledge really applicable, and yet the difference between disciplined and well-informed judgments, involving values on one hand and on the other extravagant and ignorant opinion, marks the boundary between civilization and barbarism. Developing this distinction between accumulative knowledge and philosophy, Dr. Conant refers to the confusion between what is social science and what is social philosophy. He believes that, like the service of social science and the practice of the arts of democratic government, they are vocations which cannot be combined. A major share in both advancing learning and fostering philosophy will be the responsibility of the universities, though research institutes will play an important part, and whether or not professional education is combined with research, it is essential that our intellectual leaders be in close contact with the most promising youths of the oncoming generation. We need not organize institutions of higher education into a hierarchy; but we must make it an ambition of the people to foster the spirit of free inquiry. The unity of the world of pure learning is based, not on a common method, but on a common dedication.

Prof. H. S. Taylor's paper on "The Organisation, Direction and Support of Research in the Physical Sciences" covers more the problems considered in such reports as those of the Parliamentary and Scientific Committee on "Scientific Research and the Universities". After reviewing briefly the research structure in the United States, in Great Britain and in the U.S.S.R. and commenting on the relation between research and education—the immense needs for technological and scientific training must be balanced by competent education in the liberal arts and humane studies—he asserts that the problem of direction of research is a problem of personnel and is resolved when a competent director is found. The body responsible for such selection should consist primarily of scientific men, and breadth of interest within that body should help to promote wisdom of choice. In regard to the support of research, he points out that research workers and directors have local responsibilities which, if recognized, might well broaden the bases from which private support of research might come. As regards the support of fundamental research by industry, he looks to the prosecution of fundamental studies in research institutes, co-operatively supported, and concerned also with the dissemination of research information and the training in methods of research of specially selected personnel at the graduate student level for future positions of responsibility within the industry. Speaking of State and Government support of fundamental research, Prof. Taylor insists that scientific men must be masters in their own households; the processes of mutual co-operation and assistance among the individual sciences must be multiplied, and the isolation of one science from another must progressively diminish.

In his paper "The Discovery and Interpretation of Biological Phenomena", Dr. W. Bronk, like Dr. Conant, and Marjorie H. Nicholson in her subsequent paper on "Merchants of Light: Scholarship in Arts and Letters", draws fresh inspiration from Bacon, and discusses more particularly the influence of scientific societies and institutes on teaching and research. He stresses the need in our teaching for more concern with the generalizations and relationships of science, more attention to the analytical processes, and less to the description of phenomena, particularly in training biological investigators, and pleads for clear thinking about the impediments which certain of our scientific compartments offer to effective research, and the limitations they impose on the character of the training we give our future investigators.

No summary could do justice to this suggestive address, which is practical rather than philosophical, and much the same must be said of Alan Gregg's "A Critique of Medical Research". This is somewhat more philosophical and is concerned primarily with the strategy of medical research. Commenting on an important point made, for example, in the last annual report of the Carnegie Corporation of New York, that research funds are increasingly earmarked for specific purposes by the donors, so that experience in selecting research problems and projects is on the whole too infrequent in the medical schools, he insists that the right of choosing the subject to be studied, of planning and performing some crucial experiment, belongs not to the donor or the administrator but to the investigator himself. The essential pre-occupation of wise administrators is to create and to foster the circumstances, the human relationships, in which gifted men will be most productive and prodigal of their gifts; and besides the creation of fluid research funds Dr. Gregg suggests that the creation of readerships, or posts of equal pay and tenure to professorships, but without the traditions or connotation thereof, is urgently needed to correct that characteristic of American research in which ability in research is neutralized, sterilized or otherwise wasted by the existing demands of administration and teaching. As to probable directions and characteristics of medical research in the next few decades, he instances the study of the effect of differences of environment on genetically similar organisms, genetics, biophysics and chemotherapy.

Dr. K. K. Darrow, in much the shortest paper, contributes a few crisp comments including a defence of the present system; while much the longest paper is that by H. A. Innis on "Political Economy in the Modern State". This is a major contribution to the debate to which Prof. F. Hayek's "The Road to Serfdom" has recently contributed in Great Britain, and Mr. Innis's extensive quotations from Mark Pattison may well set the contestants searching that writer anew. This sound philosophical paper has its place also in the discussion on the place of the universities

and their functions, and in Roy F. Nichol's paper on "War and Research in Social Science", Prof. R. L. Schuyler's paper on "War and Historiography" and Marjorie Nicholson's paper, there are stimulating comments and contributions to the fundamental thinking and philosophy on which alone the wise organization and direction of scientific research can be based.

# OBITUARIES

## Prof. W. E. H. Berwick

WILLIAM EDWARD HODGSON BERWICK, who died at Bangor on May 13, 1944, was professor of mathematics in the University College of North Wales from 1926 until his retirement, due to ill-health, in 1941. The title of emeritus professor was then conferred upon him by the University of Wales.

Berwick was born at Bradford on March 11, 1888, and was educated at Bradford Grammar School and at Clare College, Cambridge, of which he was a scholar from 1906 until 1910. He was bracketed Fourth Wrangler with C. G. Darwin and G. H. Livens in the Tripos of 1909 (the last year of the order of merit). In 1910 he was placed in the first class of Part II of the Tripos, and he was a Smith's Prizeman in 1911. His mathematical distinction was later recognized by a fellowship at his old College (1921–24) and by a Cambridge Sc.D. in 1925.

After two years as assistant lecturer at Bristol, Berwick went to Bangor as assistant lecturer and afterwards lecturer. Here he remained until 1920, except for two years spent in the anti-aircraft experimental section of the Munitions Inventions Department. At Bangor he had a congenial colleague in G. B. Mathews, who for many years had been almost the only worker on number-theory in England. From Bangor, Berwick went to Leeds, as lecturer and afterwards reader in mathematical analysis. He was appointed to the chair at Bangor in 1926. Shortly after this, his health began to deteriorate, but he struggled with great courage and fortitude, against increasing disabilities, to continue his teaching work and research.

Berwick's mathematical activity was concerned entirely with number-theory, the theory of equations, and topics arising out of them. His main publication was a Cambridge tract, "Integral Bases", in which he developed methods for determining an integral basis for any algebraic number-field. In particular, such a basis is determined for the field defined by $\sqrt[n]{a}$. This required the discussion of twenty-three separate cases, depending on the nature of the common factors of $n$ and $a$. The tract is a substantial contribution to algebraic number-theory, and it exhibits Berwick's interest in, and remarkable talent for, difficult enumerations and calculations. This talent was also shown in his calculations dealing with the complex multiplication of the elliptic functions.

Berwick also edited a second edition of Mathews' tract on "Algebraic Equations", to which he added appreciably. He published a number of original papers on complex multiplication and on the resolvents of quintic and sextic equations. He gave a good exposition of the latter subject in a lecture to the London Mathematical Society (printed in the *Journal*, **3**; 1928).

Prof. Berwick leaves a widow, to whom all sympathy is due.

H. DAVENPORT.

We regret to announce the following deaths:

Lieut.-Colonel L. F. Goodwin, professor of industrial chemistry and chemical engineering in the Queen's University, Kingston, Ontario, on August 15.

Prof. G. F. Stout, during 1903–36 professor of logic and metaphysics in the University of St. Andrews, on August 18, aged eighty-four.

# NEWS and VIEWS

## Mathematics at Bedford College, London: Retirement of Prof. Harold Simpson

PROF. HAROLD SIMPSON retires from the chair of mathematics at Bedford College, University of London, at the end of the present session. After a distinguished career at Oxford and a short period at Bangor, North Wales, he became head of the Mathematics Department at Bedford College in 1907 and was appointed professor there in 1912. Prof. Simpson has contributed many important articles on various topics to mathematical and scientific periodicals; in addition, he has written four valuable books. (These have appeared under the name Hilton, which Prof. Simpson gave up in 1939.) The first of these, on "Mathematical Crystallography", appeared in 1903, and his interest in this application of mathematics continues; he has served on the council of the Mineralogical Society on various occasions since 1908 and often attended the meetings of the Geology Section of the British Association. His next books, on "Finite Groups" (1907) and "Homogeneous Linear Substitutions" (1914), are in certain respects an almost essential complement to his first, having regard to the state of algebraic knowledge in Britain at the time. His other book, "Algebraic Plane Curves" (1920, 1932), is well known both to teachers and to students. Prof. Simpson has served on the council of the London Mathematical Society since 1915 and has been librarian since 1925.

Prof. Simpson played a very active and useful part in the affairs of the University of London. In particular, his colleagues will remember the skill and patience which he exercised in dealing with the business of the various committees with which he was concerned. Many hundreds of students of Bedford College will remember with gratitude his exceptional ability as a teacher; his sympathetic and understanding nature was particularly apparent to those students not so gifted in his subject, but all regard him with affection. Outside his own subject and in addition to his interest in geology, Prof. Simpson was deeply interested in architecture and in music. Students at Bedford College will remember the excursions he organized for them to various centres of architectural interest and his activities with them in the College Musical Society.

## Appointment of Dr. W. N. Bailey

DR. W. N. BAILEY, Richardson lecturer in pure mathematics in the University of Manchester, has been appointed to the University chair of mathematics at Bedford College, London. He is perhaps

best known for his work on the theory of generalized hypergeometric series; much of this was incorporated in his Cambridge 'tract' on this subject, an excellent booklet which makes pleasant reading. To him are due two new methods of obtaining transformations of such series; one is algebraic and the other uses contour integrals of Barnes' type. These methods led to various generalizations in the theory, and applications were made to Bessel functions and Legendre functions. Some of his most important work in this field concerned infinite integrals in which the integrand involved the product of three Bessel functions. The argument used an earlier result of his, that Appells' hypergeometric function of two variables could in a particular case be expressed as a product of two ordinary hypergeometric functions. This case has since been of use to other writers and has led to new researches. His most recent work, which is in process of publication, is on the problem of finding transformations of hypergeometric series of both the ordinary and the basic type. Previously, no general method of obtaining transformations of basic series had been given. His new point of view has led to new transformations of basic series, thrown further light upon them and has also led to numerous identities of the Rogers–Ramanujan type.

## Science and Industry at Manchester

THE Manchester Chamber of Commerce has done well to issue in pamphlet form (Pp. 63. 1*s.* 6*d.*) the addresses given at the four meetings on "Science and Industry" in March and April last. The pamphlet contains not only the addresses of Lord Riverdale, Dr. A. P. M. Fleming, Dr. Andrew McCance and Sir Edward Appleton, which have already been noted in these columns, but also other addresses given at the meetings, such as those of Sir Raymond Streat, Mr. A. H. S. Hinchcliffe, announcing the formation of a Joint Standing Council of the Chamber and of the University of Manchester, Mr. C. C. Renold and Mr. R. H. Dobson. Mr. C. C. Renold, following Dr. Fleming's address on "Research Workers: their Education and their Place in Industry", referred particularly to the traditional industries where the application of science should involve challenging the traditions themselves, not merely tuning them up or their further evolution. The emphasis should be on the application of what is already known rather than the extension of the boundaries of knowledge, and Mr. Renold suggested that for the medium-sized traditional concern the key move is the appointment of a scientific liaison officer with broad and general rather than specialized scientific qualifications. His job should be to recognize the problems and indicate lines worthy of investigation, and to help the practical men to apply the answers. With this fairly high-ranking appointment in the management, a re-casting of management structure might also be necessary to separate those functions of management which lend themselves to contact with the scientific liaison officer and thereby provide a convenient channel for his influence to become effective. Some re-casting of the accepted curricula of teaching may be required to provide men of the necessary breadth of scientific appreciation. Mr. R. H. Dobson, following Dr. McCance's paper on the application of research, referred to the bearing of fundamental research on the export trade of Britain, and to the necessity of creating a liaison and a free interchange of ideas and work between technical assistants and the people on the shop floors.

## Looting of Simeis Observatory

A TELEGRAM received at the Royal Observatory, Greenwich, from G. A. Shajn, member of the Academy of Sciences of the U.S.S.R., gives an account of the fate suffered at the hands of the enemy by the Simeis Observatory in the Crimea. A week or two before the Germans occupied the southern part of the Crimea, the staff of the Observatory was evacuated, the workers taking with them the object glasses of the two astrographs and part of the laboratory equipment. In May 1944, after the Crimea had been liberated by the Red Army, the Academy of Sciences sent Dr. Shajn to inspect the remains of the Observatory. He established the following facts. During September and October 1943 German specialists dismantled all the Observatory's instruments and moved them in thirty or more trucks to Simferopol, whence they were dispatched to Germany. The equipment stolen was the 40-in. reflecting telescope, the double astrograph, a new astrograph for zonal observations, a photoheliograph, three stellar spectrographs, a large cœlostat, a long-screw measuring machine, a Repsold machine, a microphotometer and two astronomical clocks.

In addition to this, much other laboratory equipment and the whole library collection of more than nine thousand negatives, and the equipment of the power station and workshop were all taken away. The wooden parts of three observatory domes were destroyed, and one of them was used as a stable. The wooden building which housed the spectrohelioscope was also destroyed, as were a number of other pavilions. On January 18, 1944, the main building of the Observatory, where a Rumanian army unit was quartered, caught fire. It continued to burn for two days, but the commander of the unit did not call out the fire brigade nor did he take any steps to extinguish the flames. British men of science will sympathize with Russian astronomers in the looting and wanton destruction of this famous Observatory.

## Tropical Diseases Investigation in New York

A RECENT article in *Nature* (May 9, 1944, p. 625) referred to the part played by parasitic diseases in war and to the realization by American physicians that these diseases constitute a grave danger to their troops overseas. Prof. H. W. Stunkard (*Ann. New York Acad. Sci.*, 44, Art. 3, 189; 1943) has referred to the absence of adequate instruction in tropical medicine or of any institution devoted primarily to work on parasitic diseases in the United States. Nuttall, Brumpt and Fülleborn, he states, thought that New York should provide the financial support for such an institution, because it is the principal shipping and commercial centre in the United States. In time of war, Prof. Stunkard points out, it is one of the chief ports of embarkation and disembarkation, so that there is acute need there for diagnostic, therapeutic and research work. The Columbia University Department of Public Information now announces that plans are being formulated which will, if they are carried out, make New York City a world centre of teaching and research in tropical medicine. Dr. H. S. Mustard, director of the DeLamar Institute of Public Health, Columbia University School of Medicine, states that a substantial beginning has been made, thanks to a temporary grant from the Macy Foundation. An additional grant from the John and Mary H. Markle

Foundation has been received for research on filariasis. Instruction in tropical medicine for medical students has been increased at the Institute, and its laboratories are now available to officers of the armed services and to others who need to go to the tropics. Intensive courses for graduates are also being provided and it is expected that very soon a full year's course will be available. There is hope that new buildings will be possible soon after the War.

Dr. Mustard echoes Prof. Stunkard's words when he says that ". . . the very business of war depends upon a successful combating of tropical diseases". Not only is the health of the fighting forces concerned, but also that of local populations in the tropics who are required for getting raw materials, building airfields and general labour. Alliances, treaties and national and trade interests are more than ever taking United States Government officials, business men and others to the tropics by ship and aeroplane, and these men, ships and aeroplanes may bring back tropical diseases and their vectors. "The universities of the United States cannot remain aloof from the realities of this situation," says Dr. Mustard. Only a few United States universities, he states, will be able to offer courses in tropical medicine, the number being limited by their position and resources. A university giving such courses should be in a great city which is a great centre of rail, sea and air transit, especially transit to and from the tropics; and it should be a recognized cultural, educational and medical centre and have international prestige and an outstanding school of medicine. Columbia University in New York City, with its unique relation with the School of Tropical Medicine at Puerto Rico and with the College of Physicians and Surgeons, would certainly seem, as Dr. Mustard suggests, to be well fitted to undertake this vitally important work.

## Solar Research in Belgium during 1942

A NOTE on this subject by Swings (*Astrophys. J.*, 99, 118; 1944) reports that the University of Liége still continues its programme of astronomical infra-red spectroscopy, and that in June 1942 a new self-recording high-dispersion spectrograph was installed in the constant-temperature basement of the solar tower. This instrument utilizes four plane echelette gratings with 15,000, 3,600, 2,400 and 1,200 lines per inch respectively, the whole spectrum from 1 $\mu$ to 20 $\mu$ being covered with a resolving power which will separate lines 1 cm.$^{-1}$ apart. A preliminary paper by Migeotte gives a general account of the results obtained from recordings of the solar spectrum in the region near 1·5 $\mu$. Here absorption lines only 1·5 A. apart can be separated, and the distinction between solar and telluric lines is relatively simple. A study of the water-vapour spectrum in this region is nearing completion, and the new instrument is now in continuous operation.

## Research in the Caribbean

PROF. J. L. SIMONSEN, director of research of the Colonial Products Research Council, Sir Robert Robinson, Waynflete professor of chemistry in the University of Oxford, and a member of the Council, are now on a visit to the Caribbean area, where they are discussing fundamental problems of research on new uses for Colonial raw materials, with specific reference to the co-ordination of the work of the Colonial Products Research Council with that of the Caribbean Research Council.

## Biography of the late Lord Cadman, F.R.S.

MR. IVOR EVANS has been entrusted with the writing of the biography of the late Lord Cadman. Readers of *Nature* possessing letters, etc., likely to be of interest are asked to forward them to Mr. Evans, c/o Mr. James Cadman, Walton Hall, Eccleshall, Staffs.

## Night Sky in September

FULL moon occurs on Sept. 2d. 20h. 21m. U.T. and new moon on Sept. 17d. 12h. 37m. The following conjunctions with the moon take place: Sept. 11d. 06h., Saturn 0·7° N.; Sept. 16d. 01h., Mercury 5° S.; Sept. 16d. 08h., Jupiter 3° S.; Sept. 19d. 00h., Mars 5° S.; Sept. 19d. 11h., Venus 5° S. In addition to the above, the following planetary conjunctions also take place: Sept. 10d. 02h., Venus in conjunction with Mars, Venus 0·5° N.; Sept. 23d. 16h., Mercury in conjunction with Jupiter, Mercury 0·1° N. Mercury is in inferior conjunction on Sept. 6, stationary on Sept. 15, and attains its greatest western elongation on Sept. 22. The times of rising of the planet at the beginning, middle and end of the month are 6h. 31m., 4h. 15m., and 4h. 32m. respectively. Venus sets at 19h. 29m., 18h. 48m., and 18h. 23m. at the beginning, middle and end of the month, and is not very well placed for observation. Mars and Jupiter are too near the sun for favourable observation. Saturn can be seen late at night or in the early morning hours; at the end of September the planet rises at 22h. The autumn equinox commences on Sept. 23d. 04h.

## Announcements

MR. C. T. GIMINGHAM has been promoted to the post of director of the Plant Pathology Laboratory of the Ministry of Agriculture and Fisheries at Harpenden, to succeed Mr. J. C. F. Fryer, who has been appointed secretary to the Agricultural Research Council.

THE Council of the Institution of Electrical Engineers has decided to continue for the present session the scheme for the admission of non-members of the Institution to any technical meeting of the Institution. Anyone who considers that his technical experience and educational attainments do not suffice to admit him to any form of Institution membership, but who nevertheless wishes to attend meetings of the Institution, can obtain from the secretary an application form, on the completion of which and on payment of a fee of 10*s*. to cover administrative costs, he will receive notices of meetings and an invitation card which will serve as a title of admission.

DR. G. LAPAGE writes: "May I correct an error in my abstract, entitled 'A Flatworm Parasite of Freshwater Trout', of the paper by J. B. Duguid and E. M. Sheppard, printed in *Nature* of Aug. 5 (p. 185). My abstract implied that Duguid and Sheppard concluded from material sent to them by Dr. Peterson, of Yell, that *Diphyllobothrium latum* is endemic in freshwater trout in the Shetlands. What these authors actually say is that 'from material kindly sent to us by Dr. Peterson of Yell, we gather that a species of Diphyllobothrium is endemic among freshwater trout in certain of the Shetland Islands'. This is, of course, very different from the statement which I attributed to them and would refer, presumably, to the larval stages".

## Penicillin-like Antibiotics from Various Species of Moulds

SINCE the demonstration of the biological and chemical properties of penicillin, an antibiotic produced by *Penicillium notatum*[1,2,3,4,5], certain other species of moulds have been shown to produce similar substances—*Aspergillus flavus*[6,7,8,9], *A. giganteus* Wehm[10], and *A. parasiticus*[11].

In the course of an investigation of moulds that have been shown by Wilkins and Harris[12,13,14] to produce antibiotics, we have found that in addition to the above-mentioned species penicillin-like substances are produced by the following:

| | National collection of type cultures No. |
|---|---|
| *P. fluorescens* .. .. .. | 6621 |
| *P. rubens* Biourge .. .. .. | 6643 |
| *P. avellaneum* Thom and Turesson | 3751 |
| *P. baculatum* Westl. .. .. .. | 3956 |
| *P. turbatum* Westl. .. .. .. | 6523 |

Of these, *P. baculatum* and *P. rubens* are morphologically similar to, and therefore possibly related to, the *chrysogenum-notatum* group, but the others are quite widely separated morphologically from that group and from each other (personal communication from Dr. W. H. Wilkins).

The antibacterial activity developed in a variety of media, including in each instance modified Czapek Dox[2], with and without corn steep liquor.

The penicillin-like nature of the antibiotic was established by the following biological and chemical properties: active against *St. aureus*, not against *B. coli*; extracted into organic solvents at $pH$ 2 and re-extracted with water at $pH$ 7; inactivated by acid and alkali; partially inactivated by heating at 100° C. at $pH$ 7 for 15 minutes; completely inactivated by penicillinase and by copper ions; all except the product of *P. turbatum*, which was not tested, were inactivated by methyl alcohol. (Some of the inactivation tests on the product of *P. baculatum* were carried out by Dr. E. Chain. We are indebted to Dr. E. S. Duthie for preparations of penicillinase.)

Thus it is becoming apparent that many species of moulds produce penicillin-like substances.

## Organic Accelerators for Enzyme Systems

IN order to determine the part played by yeast extracts in the stimulation of the respiration of various cells[1], a study was made on the possible antagonism between this respiratory stimulant and several well-known respiratory depressants. The poisons, potassium cyanide, sodium azide, amyl alcohol and urethane, react reversibly or irreversibly with particular enzyme systems of the respiratory chain. Potassium cyanide and sodium azide depress the activity of the iron oxidation catalysts, while amyl alcohol and urethane react with the dehydrogenating system.

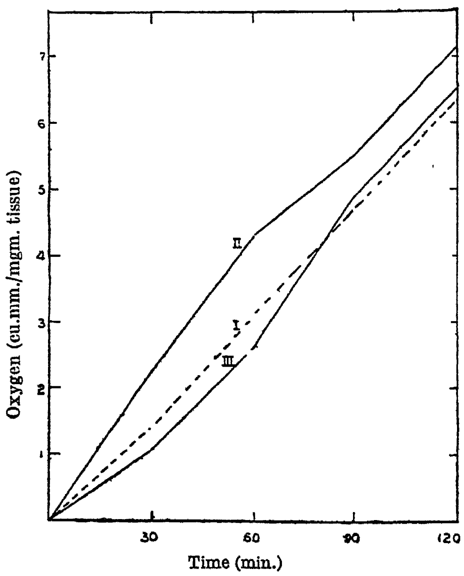

Fig. 1. EFFECTS OF YEAST EXTRACT AND SODIUM AZIDE ON RAT LIVER RESPIRATION
Curve I, control. Curve II, yeast extract initially present and sodium azide added at 60 min. Curve III, sodium azide initially present and yeast extract added at 60 min.

In Fig. 1 is shown the antagonism between yeast extract (6 mgm./ml.) and $M/1,050$ sodium azide on rat liver respiration. The oxygen uptake was determined in Ringer-phosphate glucose solution at a temperature of 37·5° C.[1]. In one set of experiments, 1 ml. of yeast extract (18 mgm./ml.) dissolved in Ringer-phosphate glucose was placed in the flask at the beginning of the experiment. Addition after 60 minutes of 1 ml. of $M/350$ sodium azide in Ringer-phosphate glucose offset the stimulation caused by the extract and brought the rate of oxygen uptake back to that of the control. In the other set of experiments, the depression of respiration due to sodium azide was offset completely when 1 ml. of yeast extract was added from the side arm. Qualitatively similar results were obtained with potassium cyanide. No antagonism could be found between the yeast extract and poisons such as amyl alcohol and urethane. We suggest, therefore, that the yeast extract stimulation occurs at the same part of the chain blocked by cyanide and azide, namely, cytochrome oxidase. Yeast and rat skin have behaved in a manner qualitatively similar to liver.

Since cytochrome oxidase is known to be an iron porphyrin enzyme containing a hæmin-like prosthetic group, it was thought desirable to study more closely the activity of the yeast extracts on simpler systems containing such iron enzymes as horse radish root

peroxidase and liver catalase. In the accompanying table is given the results of the sodium azide–yeast extract antagonism on the oxidation of pyrogallol by peroxidase.

ANTAGONISTIC EFFECTS OF SODIUM AZIDE AND YEAST EXTRACT ON PEROXIDASE ACTIVITY.

| Flask | Total purpurogallin produced (mgm.) | P.N. |
|---|---|---|
| I. Control .. .. .. .. | 16·0 | |
| | 16·2 | 0·21 |
| II. Control, yeast extract (1·5 gm.) .. | 20·5 | 0·27 |
| III. Control, 1 ml. sodium azide (0·50 *M*) .. .. .. | 10·2 | 0·13 |
| IV. Control, yeast extract, sodium azide .. .. .. .. | 14·5 | 0·19 |

The method used in determining peroxidase activity was that of Willstätter modified by Bancroft and Elliott[2]. The yeast extract partially offset the sodium azide depression and accelerated the purpurogallin production approximately 26 per cent above control. The extract was much more effective against potassium cyanide. The depression caused by lower concentrations of both poisons could be offset completely by the extract. The extract exerted a slight but definite peroxidase action in the absence of added enzyme.

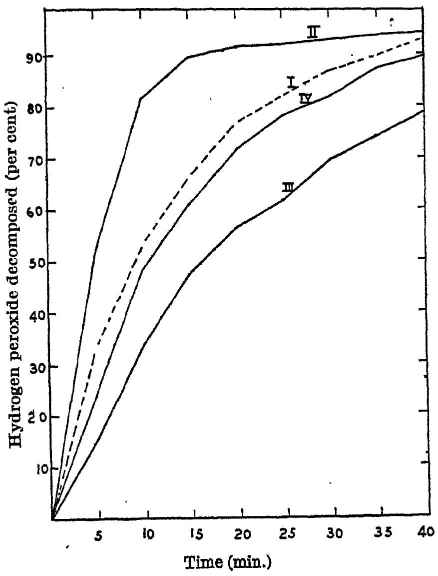

Fig. 2. EFFECTS OF YEAST EXTRACT AND POTASSIUM CYANIDE ON DECOMPOSITION OF HYDROGEN PEROXIDE BY CATALASE.
Curve I, control. Curve II, control + yeast extract. Curve III, control + potassium cyanide. Curve IV, control + potassium cyanide + yeast extract.

In Fig. 2 is shown the stimulation of hydrogen peroxide decomposition by catalase in the presence of the extract, and also the ability of the extract to antagonize the potassium cyanide depression. The method employed for the calculation of catalase activity was that of Euler and Josephson[3]. Concentrations of yeast extract and potassium cyanide were 1 mgm./ml. and $2{\cdot}5 \times 10^{-3}$ *M*., respectively. The yeast extract did not decompose hydrogen peroxide in the absence of catalase.

The experiments on peroxidase and catalase indicate that the yeast extract did not function as substrate for the enzymes. It did not possess catalase activity in itself and showed but a very slight peroxidase activity. Significantly increased activities were observed only in the presence of the enzymes. The yeast extract may be considered to contain organic accelerators for iron porphyrin enzymes. It is suggested that the extract contains organic iron compounds the molecular size of which lies somewhere between iron sulphate and hæmin, and which can function as additional prosthetic groups for the protein of the enzyme (apoenzyme). This possibility is being investigated.

## Effect of Caramelized Fructose on the Stability of *l*-Ascorbic Acid

THE investigation of the effect of caramelized fructose on the stability of *l*-ascorbic acid was suggested by the demonstration that caramelization of lemonade powders at high storage temperatures was due to fructose which was formed from sucrose by hydrolysis, made possible by the liberation of water of crystallization of citric acid[1]; and also by the fact that a darkening of colour and a loss of ascorbic acid are associated changes in orange juice concentrate, although the relationship between the two processes is by no means clear.

That this matter may be important in relation to the deterioration of foodstuffs in warm climates is indicated by the fact that, at 98° F. (36·7° C.) and higher temperatures, pure fructose (both solid and aqueous solution) caramelizes spontaneously. As circumstances will not allow of the completion of this work for some time, it was deemed of sufficient interest and possible importance to merit a short statement.

A sample of B.D.H. fructose which had caramelized on keeping was used for the tests carried out under aerobic conditions reported below. A 1 per cent aqueous solution gave a galvanometer reading of 81 with an Evelyn photo-electric colorimeter. Tests—chiefly under anaerobic conditions—were also carried out with samples of Kahlbaum and of Baird and Tatlock fructose which had likewise caramelized on keeping. 1 per cent solutions gave galvanometer readings of 75 and 23 respectively. Pure fructose was prepared by recrystallizing from an alcoholic solution which had been treated with Merck pulverized animal charcoal until all traces of colour had been removed.

Ascorbic acid was estimated by titrating with 2:6-dichlorophenolindophenol, which was not reduced by the samples of caramelized fructose used. This is in contrast to the products of caramelization brought about by the action of alkali[2].

Glassware and materials were sterilized except for ascorbic acid and fructose. This was necessary owing to the liability to bacterial and fungal infection, especially in the solutions containing pure fructose and ascorbic acid.

10 per cent solutions of pure and of caramelized fructose were made up to contain 50 mgm. ascorbic acid per 100 c.c. solution. About 24 c.c. solution was put into 50 c.c. stoppered containers. Thus the available oxygen was much in excess of the amount

needed to oxidize the 13 mgm. ascorbic acid present, since complete oxidation would need less than 1 c.c. of oxygen. Also the containers were opened up at intervals for titration.

In most of the tests the solutions were stored at 50° F. (10° C.). The rate of loss of ascorbic acid was found to be too rapid for convenience at 85° F. (29·4° C.).

The accompanying table summarizes the results of a number of experiments. It is clear that there is a greater loss of ascorbic acid in solutions of caramelized fructose than in solutions of pure fructose. The contrast is emphasized by the direct comparisons for the second, tenth and seventeenth day intervals.

PER CENT LOSS OF ASCORBIC ACID UNDER AEROBIC CONDITIONS AT 50° F. (10° C.).

| Days | Pure fructose | Caramelized fructose |
|---|---|---|
| 2 | 3·1 | 32·9 |
| 5 | — | 46·6 |
| 7 | 12·3 | — |
| 8 | — | 68·5 |
| 10 | 18·65 | 75·2 |
| 14 | 20·3 | — |
| 17 | 31·0 | 100·0 |

The question naturally arises as to whether caramelized fructose has a destructive effect on ascorbic acid under anaerobic conditions. Tests, using various techniques, were carried out with the three samples of caramelized fructose mentioned above. The results so far obtained are not sufficiently precise to merit detailed statement; taken by and large, however, there can be little doubt of a destructive effect, but it is also clear that the rate of destruction is very much slower. The destructive effect under anaerobic conditions is also indicated by the decided differences in rate of loss of ascorbic acid brought about by the different samples of caramelized fructose under anaerobic conditions.

## Production and Release of Nicotinamide by the Intestinal Flora in Man

AN investigation into the daily elimination of nicotinamide methochloride in healthy human beings[1] revealed a considerable discrepancy between this elimination and the daily intake of nicotinamide on current diets, as calculated from assays by Williams[2] in the United States and Kodicek[3] in Great Britain. Najjar and Holt[4] have shown that aneurin can be produced by the intestinal flora, which is thus capable of influencing the aneurin household of the body in a decisive manner. These findings suggested a similar mechanism for the production of that part of the nicotinamide which cannot be accounted for from the daily food intake.

This possibility was examined in a preliminary experiment by 'sterilizing' the alimentary tract of two persons with sulphaguanidine. The elimination of nicotinamide methochloride was estimated before, during and after the dosing period. A considerable drop in the nicotinamide methochloride elimination occurred during the dosage. We then proceeded to investigate this effect on a larger scale with eight volunteers. Five persons (three healthy and two chronic pellagrins) were given succinyl-sulphathiazole, while three persons (two healthy and one chronic pellagrin) received sulphathiazole to serve as a control. Diet and environmental conditions were uniform throughout the whole experimental period. The daily nicotinamide methochloride output was estimated before, during and after the treatment, blood and urinary levels of sulphathiazole were determined and test doses of nicotinamide were given twice to each subject, at the end of the dosing period and a week later, once orally and once parenterally.

The following points emerge from these experiments:

(*a*) There was a sharp drop of nicotinamide methochloride elimination during dosage with succinylsulphathiazole from the first day of dosing onwards, while the control group on sulphathiazole showed no significant change. The extent of the decrease in the nicotinamide methochloride output varied individually between 50 and 100 per cent, probably with the degree of sterilization of the intestines. The reduction in methochloride output was greater with succinylsulphathiazole than with sulphaguanidine and amounted on the average to 70 per cent in the healthy and 95 per cent in the pellagrous subjects.

(*b*) Sulphathiazole levels in blood and urines were considerably higher in the control group. The possibility of a direct interference of sulphathiazole with the nicotinamide metabolism is therefore excluded.

(*c*) Nicotinamide given at the end of the dosing period produced the usual rise in methochloride elimination in the healthy subjects, which proved that the formation of nicotinamide methochloride is not impaired by the drugs administered.

(*d*) The responses to nicotinamide administration varied according to the mode of administration; five subjects, including all three pellagrins, showing lower responses to the oral dose than to subcutaneous injection. The considerably lower response to oral dosage in all three pellagrins points to an absorption defect, a factor which has long been regarded as one of the causes of pellagra[5].

The most obvious interpretation of the marked reduction in nicotinamide methochloride output during administration of sulphaguanidine and succinylsulphathiazole is to assume that normally a synthesis and release of the vitamin by the intestinal flora takes place, and that this mechanism is impaired by the bacteriostatic action of the drugs. It is improbable that the drop in nicotinamide methochloride elimination could have been due to greater utilization of nicotinamide, since more sulphathiazole was circulating in the subjects receiving sulphathiazole, who showed no decrease in methochloride output, than in those receiving succinyl-sulphathiazole.

The gap between the dietary intake of nicotinamide and the elimination of nicotinamide methochloride referred to above appears, therefore, to be filled by the nicotinamide produced and released by the intestinal flora. Furthermore, it seems from present and previous work[1] that the quantity thus provided for human utilization can amount to as much as 80 per cent of the daily uptake.

This new factor is capable of explaining a number of previously reported inconsistencies in the etiology and therapy of nicotinamide deficiency diseases, particularly of pellagra. Roussel[6] and later Goldberger[7] and many others have insisted on the pellagra-preventive action of milk and milk products, which are notoriously poor in nicotinic acid[8]. Conversely,

maize, which is the staple food of many districts where pellagra is endemic, is not more deficient in nicotinic acid than wheat[8]. These paradoxes could easily be explained by assuming a primary effect of these foods on the intestinal flora. Thus, taking the case of milk, the following mechanisms may be involved.

(1) Milk protein provides the necessary building-stones for the bacterial synthesis of nicotinamide. This would appear possible in view of the work of Bovarnick[9], who demonstrated that mixtures of certain amino-acids and organic amides, which are present in significant amounts in milk protein, yield nicotinamide when heated.

(2) Milk as such provides a favourable nutritional medium for some types of intestinal bacteria, with a consequent increase in their general activity, including vitamin synthesis.

(3) Milk, by influencing certain physico-chemical factors, such as $pH$, favours the development of some particular strains of the intestinal flora responsible for the production of nicotinamide.

Maize, on the other hand, might produce the opposite effect on the intestinal micro-organisms.

Regarding nicotinamide deficiencies other than classical pellagra, particularly the acute confusional states described by Cleckley, Sydenstricker and Geeslin[10] in America and Gottlieb[11] in Great Britain, the suggestion by one of us (R. B.[12]) that confusional complications following sulphaguanidine therapy might have been due to a temporary aneurin deficiency should now be implemented by postulating an even more likely occurrence of an acute nicotinamide deficiency.

The literature contains numerous references to rashes following sulphaguanidine and succinylsulphathiazole therapy. While most of them have undoubtedly an allergic basis, a number have been put down to other causes and have even been likened to pellagrous dermatitis[13].

On the basis of our findings we would also like to endorse Najjar and Holt's[4] suggestion that the use of sterilizing sulphonamide drugs requires careful attention to the vitamin B status of the patient.

A detailed report of these experiments will be published elsewhere.

We are indebted to Dr. W. A. Caldwell for permission to carry out the larger experiment at West Park Hospital, Epsom, and Dr. S. W. Hardwick for the clinical care of the subjects under investigation.

## Production of a Soluble Pectinase in a Simple Medium by certain Plant-Pathogenic Bacteria belonging to the Genus Pseudomonas

IT has generally been assumed that plant-pathogenic bacteria are able to decompose pectin[1]. Thaysen and Bunker[2], however, limit themselves to the following statement: "to the aerobic pectin decomposers belong some of the many plant-pathogenic bacteria . . . In most of their biochemical reactions they resemble the *Pseudomonas fluorescens* group or those *Bacterium coli* forms which are regularly found in grass and hay". Although many plant pathogens do in fact belong to the genus Pseudomonas[3], including organisms responsible for soft rot[4] as well as necrotic lesions, yet no detailed study of the pectin-degrading powers of these green-fluorescent bacteria seems to have been made, nor has it been shown that they resemble the soft-rot organisms of the Bacterium group (for example, *B. carotovorum*) in producing an exo-cellular pectinase[5,6].

Pseudomonads have the simplest of growth requirements, and the pectin-ammonium salt medium devised by Coles[7], with one slight modification, is quite suitable for the demonstration of their pectin-degrading powers. The modification, following Waksman and Allen[8], lies in the substitution of pectic acid for pectin, partly for the reason that it is more easily recognized through its characteristic, gelatinous and insoluble calcium salt, and partly because only one enzyme, pectinase, instead of two, is concerned in its immediate breakdown. Waksman and Allen used a commercial polygalacturonic acid preparation as substrate. This material is not available here, but a suitable pectate medium can easily be prepared from B.D.H. citrus pectin in the following way: a 0·4 per cent solution of pectin in decinormal sodium hydroxide is left overnight at 20° in order that the methyl ester groups may be hydrolysed[9]. Sodium ammonium hydrogen phosphate (0·05 per cent) is then added and the medium brought to $pH$ 7·0[10] by the careful addition of $2N$ hydrochloric acid. Finally, after addition of potassium chloride (0·02 per cent), magnesium sulphate (0·02 per cent) and a trace of ferrous sulphate the medium is tubed and sterilized by steaming.

All the pseudomonads tested grew readily in this medium at 24°, even from a small inoculum, and could be maintained in serial cultivation in it without production of either acid or gas, the $pH$ remaining between 6·5 and 8. But good growth did not necessarily mean extensive degradation of soluble pectate, for out of thirty-five strains so tested, most of which were reputedly pathogenic and also fluorescent, only six actually degraded the pectic acid in a reasonable time. After three weeks incubation following a heavy inoculation, the metabolism solutions from these strains, after removal of bacteria by centrifuging, gave no appreciable precipitate with acetic acid and calcium acetate, whereas the metabolism solutions from the other strains still gave a copious gelatinous precipitate of calcium pectate. The six active strains were distributed as follows: *Ps. mors-prunorum* Wormald[11] (one out of eight strains); *Ps. syringæ* derived from pear (two out of eight); *Ps. marginalis*[4], *Ps. cerasi* and *Ps. tabaci* (one out of one in each instance). In addition to these six active and thirteen inactive strains the following

were also inactive: *Ps. prunicola* (two strains); *Ps. syringæ* derived from sources other than pear (three); *Ps. phaseolicola* (one); *B. tumefaciens* (two); *X. pruni* (one); ordinary saprophytic strains of *Ps. fluorescens* (seven).

Of the six active strains, three were outstanding, namely, *Ps. marginalis*, *Ps. cerasi* and one *Ps. syringæ* strain derived from pear, but *Ps. marginalis*, the only soft-rot organism tested, was the only strain which would grow from a small inoculum and simultaneously completely degrade all the pectate in the medium. Several strains of *Ps. mors-prunorum*, unlike the saprophytic strains, did, however, produce an appreciable degradation of pectate in thirty days when growing from a small inoculum. It would seem, therefore, that the soft-rot organism is more efficient in the degradation of pectate than even the more active of the strains responsible for necrotic lesions, which in turn are more active than any of the saprophytic strains here studied, all this being quite in accordance with legitimate expectation.

Each of the three active strains mentioned above produced an exo-cellular pectinase which could be precipitated by alcohol when all the pectate had been decomposed and the bacteria then removed by centrifuging. The simple medium here used, which contains no organic source of nitrogen, has obvious advantages over the complex media previously used in attempts to isolate soluble bacterial pectinase[5,12,13]. It is of interest that the Pseudomonas pectinase is active at $p$H 7–8, whereas mould pectinase acts best under much more acid conditions[8,14]. A further study of the bacterial enzyme is being made.

I wish to thank Mrs. D. H. Oxford, a special research officer of the Agricultural Research Council, lately affiliated to the East Malling Research Station, for most of the cultures used in the above study. Some were isolated by her and others by Drs. H. Wormald and H. B. S. Montgomery of the Station, to whom I also offer my thanks. The cultures of *Ps. marginalis*, *Ps. cerasi*, *Ps. tabaci* and *Ps. phaseolicola* were received from Dr. W. J. Dowson through Dr. Montgomery. It should be added that the generic names Bacterium, Pseudomonas and Xanthomonas are used in this communication in the sense advocated by Dowson in 1939[3].

## Reaction of Formaldehyde with Keratin

AN earlier communication[1] described the reaction of keratin fibres with boiling solutions of formaldehyde $p$H 2–10. For reasons connected with other work, buffer solutions one tenth the concentration described by Britton[2] were used, and since adequate buffering action could not be obtained at $p$H 1 under these conditions, no results were published for highly acid solutions of formaldehyde. The action upon keratin fibres of formaldehyde buffered to $p$H 1·0, 5·0 and 10·5 with full strength buffers is now described.

(1) *Normal Keratin.* Purified human hair fibres from the sample used in earlier experiments were boiled under reflux for 1 hour in solutions of 2 per cent formaldehyde $p$H 1·0, 5·0, 10·5. Full strength Walpole ($p$H 1·0, 5·0) and Ringer ($p$H 10·5) buffers were used[2], excess reagent being removed from the treated fibres by a 40 hours wash. The supercontraction of the fibres in boiling 5 per cent sodium metabisulphite was then measured in the standard way, three fibres being used for each $p$H value. Results, together with those for fibres boiled in buffer solutions alone, are given in Table 1.

TABLE 1.

| $p$H | 1·0 | 5·0 | 10·5 |
|---|---|---|---|
| % Supercontraction: | | | |
| Formaldehyde treated | 2·0 | 25·0 | 1·0 |
| Buffer treated | 25·0 | 21·0 | 1·0 |

Supercontraction of untreated hair = 26·0 ± 1·0 per cent.

It is obvious, therefore, that new linkages resistant to boiling metabisulphite were present in hair which had been boiled for 1 hour in 2 per cent formaldehyde at $p$H 1 or 10·5. The low supercontraction of fibres boiled in buffer solution at $p$H 10·5 is due to the presence of new linkages formed by secondary reactions of the sulphenic acid groups of hydrolysed disulphide linkages[1,3].

(2) *Deaminated Keratin.* Human hair fibres were completely deaminated in van Slyke's reagent[4]. The fibres were then treated with formaldehyde as in (1), except that in this case the reaction occurred in the presence of molar sodium sulphate. Table 2 gives the supercontractions of these fibres.

TABLE 2.

| $p$H | 1·0 | 5·0 | 10·5 |
|---|---|---|---|
| % Supercontraction: | | | |
| Formaldehyde treated | 15·0 | 33·0 | 5·0 |
| Buffer treated | 36·0 | 33·0 | Fibre destroyed |

Linkages resistant to boiling 5 per cent sodium metabisulphite, therefore, are formed in deaminated fibres on boiling in 2 per cent formaldehyde at $p$H 1 or 10·5.

The load/extension curves of fibres were determined[1] before and after deamination, and it was found that the reduction in the work required to stretch fibres 30 per cent of their original length was 31·0 ± 1·0 per cent. After standing overnight in distilled water, the fibres were boiled for 1 hour in 2 per cent formaldehyde at $p$H 1·0, 5·0, 10·5 in the presence of molar sodium sulphate, washed for 40 hours and then restretched. The further changes in work of formaldehyde and buffer treated fibres appear in Table 3.

TABLE 3.

| pH | 1·0 | 5·0 | 10·5 |
|---|---|---|---|
| % Change in work: | | | |
| Formaldehyde treated | +11·0 | +6·0 | −58·0 |
| Buffer treated | +1·0 | −1·0 | −61·0 |

On comparing these results with those in Table 2, it will be seen that no simple relationship exists between the effect of new linkage formation on the resistance of fibres to extension and on the supercontraction of fibres in boiling solutions of sodium metabisulphite.

## The Concept of Force

MR. JOSHUA C. GREGORY'S statement[1] "When a motor-car turns sharply round a corner the passenger feels as if he were shoved but not as if a thing shoved him" suggests that he has not clearly analysed the experience. The main sensations (other than visual) are of contact and pressure on the side of the body on the outside of the curve; in other words, of a force as ordinarily experienced acting towards the centre, in the same direction as the acceleration. The sensations are exactly similar to those felt in the back when a car accelerates rapidly. If there is no contact there is no sensation and no force, and the passenger continues in his previous uniform motion in accordance with Newton's First Law. In the same way, with high acceleration the head and shoulders which are not in contact with the back of the seat move relatively backwards over the top of this and experience no sensation of force.

W. B. YAPP.

Manchester Grammar School,
Manchester, 13.

[1] *Nature*, 154, 24 (1944).

MR. JOSHUA C. GREGORY'S letter under this title[1] seems to me misleading. A "notion of force" without a "notion of matter" appears to me a contradiction. Without matter there can be no motion and therefore no acceleration; and without acceleration there can be no force since force denotes a mass-acceleration product.

When I go round a sharp corner in a motor-car I definitely experience the sensation of being shoved by the seat.

To describe forces as "immortal" or "imperceptible" strikes me as idealist nonsense. A force lasts just as long as the matter with which it is associated has acceleration; the force associated with the retardation of a hammer on one's thumb is perceptible enough. "Disembodied force" is as meaningless as "matterless motion". Let us keep these anthropomorphic and idealist notions of force out of physics; force would exist in a lifeless universe.

JOHN CASE.

Clearbrook,
Nr. Yelverton,
S. Devon.

[1] *Nature*, 154, 24 (1944).

THE description of force, gathered from the "Hermetica" into my communication in *Nature* of July 1, p. 24, does not, as such, ask Mr. John Case to believe in "immortal" and "imperceptible" forces, or to adopt any "anthropomorphic and idealist notions". In 1864 Colding connected immaterial and imperishable forces with the perpetuity of energy which had been clear to him since 1840, and there is at least a hint at the modern conservation of energy in the immortal forces of the "Hermetica". Those who still refuse to reduce causal *efficacies* to mere regular routine can sympathize with the *working* of the Hermetical forces. The letter, however, only suggests that the Hermetical concept of force embodies a recognizable distinction in sensory experience. The concept can do this however violently modern thought disclaims it in other respects.

Muscular sensations themselves, the suggestion runs, only produce a sense of what Prof. Price calls "pure force, disembodied force as it were". This corresponds to the incorporeal nature of the Hermetical force. Sensations of contact are essential to complete the sense of the resistant or propulsive material thing. The Hermetical forces only work in bodies; this corresponds to the very usual combination of muscular and contact sensations. Cut out a man's contact sensations, leave all his other sensations in, he will then, according to the suggestion, have only a sense of "disembodied force" and have no sense of material things. If this sense of pure or disembodied force is actually felt in the centrifugal experience, as Price suggests, the phrase "disembodied force" is not "meaningless", as Mr. Case asserts.

Mr. W. B. Yapp concentrates on a denial of this sense of pure force when a motor-car corners rapidly or accelerates sharply. When a motor-car turns quickly, a passenger on the back seat is thrown somewhat laterally and *feels*, or may feel, as if an immaterial force throws him, as if he is shoved without being shoved by a material shover. This is the experience of the writer and presumably of Prof. Price. Some people stress unexpectedness—they have this sense of pure force when the car takes them unawares as it corners quickly. They have a similar experience during a sharp acceleration backwards or forwards. There seem also to be analogous aeroplane experiences. When I am 'centrifuged' in a motor-car I do not "definitely experience the sensation of being shoved by the seat", as Mr. Case does, nor do I sense a contact push on my free side when I am pressed against the resistant side of the car, as Mr. Yapp seems to do.

Some people at least confess to a momentary feeling of "what on earth is happening!" and an evanescent whiff of uncanniness sometimes rushes through me. Mr. Case and Mr. Yapp may dissent because the inveterate tendency to connect pushes or pulls with contacts predisposes them against a recognition of the actual, though usually momentary, experience. Many 'centrifuged' passengers do seem to glimpse, if only for a moment, the sense of disembodied forces that might be habitual if there were no contact sensations. The experience seems to occur, however the somewhat elusive concept of force is finally assessed.

Prof. Price, of course, though he gave me a cue, is not responsible for the use made of it.

## Fatigue in Selenium Rectifier Cells

THE effect described by Mr. J. S. Preston in his letter in *Nature* of June 3[1] may be connected with the increased departure from linearity of response which Dr. W. R. G. Atkins and I[2] found to occur in a number of these cells when illuminated by light of wave-length greater than about 0·66 μ. We were interested in the use of these cells to measure daylight, especially under water, where very large changes of illumination occur and optical methods of varying the exposure of the cell are very inconvenient. Long range and large maximum illumination were therefore essential, and the photometer bench used gave a range of 1 to 725. A filament lamp behind a water cell 4·4 cm. thick gave a maximum illumination estimated at some 15,000 lux when no colour filter was used. Schott *BG* 12, *RG* 1 and *RG* 5, Corning Green and Zeiss 966/8 filters, singly or combined, enabled different spectral regions to be tested. Fatigue effects were reduced to the utmost by keeping the cell in the dark except for the few seconds needed to balance the Campbell-Freeth circuit by which the current was measured. The comparative steadiness of the balance seemed to show that in this case fatigue was unimportant. We did not notice enhanced fatigue in red light, possibly because we expected a small fatigue effect due to the warming of the cell circuit by the comparatively intense deep red and near infra-red radiation transmitted by the red filters.

Under these conditions we found that for a Weston cell and light of wave-length below about 0·66 μ, the sensitivity, as measured by the Campbell-Freeth zero resistance circuit, was nearly constant up to about 100 μamp., showing, in fact, a small rise with current up to a few microamperes, as found for some cells by other workers. For wave-lengths above 0·66 μ, however, the sensitivity commenced to fall at about 1 μamp., and had fallen by 15 per cent at 100 μamp. Another Weston cell showed a similar effect, and eight electro cells each showed it to an enhanced degree.

Adding to the resistance of the circuit of course increases the departure from linearity, but we were somewhat surprised to find that for each cell tested the inclusion of 1,000 ohms in the circuit produced a fall in current depending only on the initial current, and not at all on the colour of the light to which it was due. We accordingly suggested that the red light effect was of a primary nature, and due to the existence in the selenium cells of a photo-electric threshold near 0·66 μ, causing a tendency to saturation in the current produced by intense illumination of longer wave-lengths.

The increase in the transparency of selenium near 0·64 μ may be connected with a reduction in the number of photo-sensitive and hence light-absorbing electrons as we passed through that spectral limit. This limit, as found by Mr. Preston for the fatigue effects, is so close to our approximate limit for the curvature effect that it seems probable that the two effects are closely connected.

H. H. POOLE.

Royal Dublin Society. June 16.

[1] *Nature*, 153, 680 (1944).

[2] *Sci. Proc. Roy. Dub. Soc.*, 22, 393 (1941).

---

THE results to which Dr. Poole refers seem certainly to be related to the fatigue effects which we have noticed. During a recent visit to this Laboratory, Dr. Atkins directed our attention to these results and we discussed them in some detail.

Taken in conjunction with our own, they point to a close correlation between various properties of the cells, as Dr. Poole suggests, and there now seems good reason to believe that the basic common factor is the existence of a photo-electric, and an associated transparency, threshold in the neighbourhood of 0·66 μ or 0·64 μ. The way in which this factor enters into the action of the cell is certainly of practical interest and may be of fundamental importance. Our suggestion that the comparatively deep penetration of red light into the selenium results in a kind of space-charge retarding the emission of electrons from the deeper layers is, of course, only tentative; but such a mechanism would provide for both the non-linearity and the fatigue effects together, provided the space-charge is not built up instantaneously. This supposition recalls also the kind of fatigue exhibited by the older resistance type of cell.

The subject of fatigue merits careful investigation and we hope to carry out further work upon it.

J. S. PRESTON.

Light Division, National Physical Laboratory. July 4.

## Relation between Dissonance and Context

IN an attempt to meet some of the criticisms made of our previous work on the effect of musical context on dissonance[1] a new experiment has been carried out.

A single 'dissonant' chord, the seventh on the sub-dominant (when in *C* Major), second inversion ($c_0\ a_0\ f'\ e''$, according to the tone nomenclature given by Myers[2]), was used throughout as the chord to be investigated, and will be called the 'test chord'. Mr. C. G. Gray suggested this chord, and offered several contexts for it. A number of other passages in which it appeared were found in well-known works, with an additional passage composed by Mr. Gray and slightly altered by the writers. Altogether there were fourteen passages: two by Chopin, one by Weinberger, nine by Greig, one from a traditional air and one by Mr. Gray. The test chord, though, of course, it was not always in *C* Major, did always consist of the same four identical notes.

The passages were played on the piano to fifty students (43 women and 7 men). The aim of the experiment was explained beforehand, and the subjects were asked to avoid judgments of liking and disliking and to concentrate upon consonance and dissonance. As each passage was played by one of the experimenters (P. A. D. G.), the other (R. W. P.) raised his hand when the test chord was sounded and then immediately lowered it again. Each passage was played over in this way often enough for all the subjects to be satisfied that they had identified the test chord and rated it on a scale +3, +2, +1, 0, −1, −2, −3, from very consonant to very dissonant.

The subjects had all received instruction in the psychology of sound and had done the Oregon and other music tests. They also filled in a questionnaire on degree of musical interest. Their average score for on the Oregon test was 77/96, and the scores of this test correlated +0·576 ($p<0·01$) with the questionnaire results converted into a quantitative form. These points show that the musical ability of the group was high. The subjects were astonished

when told afterwards that they had rated the same chord throughout.

The ratings of the test chord were tabulated and their frequencies are shown in the accompanying table:

| Rating | +3 | +2 | +1 | 0 | −1 | −2 | −3 |
|---|---|---|---|---|---|---|---|
| Frequency | 62 | 119 | 101 | 52 | 164 | 124 | 78 |

This distribution of frequencies is quite incompatible with the possible hypothesis that the test chord was of constant or even of approximately constant dissonance-level. They are significantly different from a purely chance distribution of the total of 720 ratings into the seven classes, and show that the chord was most often considered moderately dissonant.

Analysis of variance of the table of ratings showed that the variance due to differences between contexts outweighed the error variance by an amount of which the probability was less than 1 in 1,000. This result is very strong evidence that the dissonance-level of the test chord varied with its musical setting. The variance due to differences between individual subjects was significantly greater than the error variance, and significantly lower than the variance due to differences between contexts. This is evidence that the musical standards, opinions or preferences of the subjects were factors in determining dissonance level, but of far less importance than the effects of varying the musical context.

It may be suggested that 'dissonance-level' is a *Gestalt* phenomenon. It is determined by several factors, of which the chief are (*a*) the physical composition of the chord, (*b*) the 'schemata' in our minds which arise from experience and depend on musical ability, on training and on tradition, and (*c*) the musical effect, import or intention of the passage as a whole. The latter was the outstanding influence in this experiment, and it has been dealt with in a letter to us by Mr. John L. Dunk. This is too long for quotation, but in it he has given passages from Beethoven, Elgar and Wagner, showing that sometimes a chord 'theoretically' correct may be excessively harsh in relation to the musical import of the context; whereas in other passages a dissonance which could scarcely be defended in theory, at least at the period when it was composed, may be completely appropriate from the point of view of the import of the passage as a whole.

We are indebted to Mr. Joseph F. Simpson for his help with the calculations.

## Science and the Fisheries

IN his admirable discourse at the Royal Institution[1] Michael Graham declares with good reason that "the Great Law of Fishing is that unlimited fisheries become unprofitable", and he deduces that "the only adequate measure to conserve the fishery is to set some limit to the amount of fishing". Fishery legislation, with its restrictions upon fishing areas, upon the mesh of nets, upon the size of fish landed and so on, has not succeeded in staying the downward drift, and more restriction is necessary. The Great Law of fishery legislation, based upon sound scientific advice as things stand, is restriction.

Now an outstanding lesson of the United States contribution to the International Fisheries Exhibition of 1883 and its Conferences, to which Graham refers, was, so far at any rate as freshwater fisheries are concerned, the reverse of restriction. The United States Fish Commission realized that "were the governmental policy directed towards preventing the people from catching the few [fishes] left after generations of improvidence, the expense would be enormous, while such laws would be evaded constantly, and almost with impunity"[2]. The Commission therefore dropped a negative for a positive policy and decided "to expend a comparatively small amount of the public money in making fish so abundant in the rivers and lakes that the public itself may fully and freely enjoy the result"[2]. That was the ideal.

May we not look to the same sort of positive policy in regard to sea fisheries, instead of accepting as axiomatic that restriction of fishing is the only adequate means of keeping up the fish population? Scientific workers know enough about the fundamental relations between the chemistry and physics of the sea and the organisms that live in it to attempt some control of these for the benefit of the fisheries. On a small scale the success of such control, by the addition of chemical nutrients, has been indicated by the work on oyster culture in Norway, and by the limited and still incomplete but developing experiments of Dr. Gross and his colleagues in Loch Sween in Argyllshire. In fresh waters, where the basic problem is similar, I am told by the chief of the Biology Division of the United States Department of Agriculture, Edward H. Graham, that it has been encouraging farmers to add chemical nutrients to ponds for the purpose of increasing growth of selected species of fishes, and thus increasing the war-time supply of food.

If the Loch Sween experiments in their wider range are successful, they will point to the possibility of improving sea fisheries instead of curtailing them. If they are not successful, other experiments with the same end in view should be considered. My plea is that scientific workers in fishery matters should turn more attention to the progressive and productive, rather than to the restrictive, possibilities. There is one important point, however, which must be borne in mind. In his paper on the fishery industries of the United States, read at the Conference associated with the International Fisheries Exhibition of 1883, Prof. G. Brown Goode pointed out that "public fish culture is only useful when conducted upon a gigantic scale—its statistical tables must be footed up in tens of millions" [of fishes, not dollars]. In the sea the scale must be vastly greater, it must be international; so that we may be allowed to speculate upon a day, perhaps not many years hence, when the International Fisheries Commission of the nations bordering the North Sea may discuss, along with its programme of researches, the allocation of the sums to be contributed by each nation for chemical nutrients, in the assurance that these will support a larger fish population and an increased fishing fleet in the North Sea.

# RESEARCH ITEMS

## Inheritance of Tuberculosis

IT has been difficult in the past to evaluate correctly the evidence for the inheritance of tuberculosis or of tendencies which might facilitate infection. Obviously twins provide material which might give valuable evidence on this matter. The analysis of twins has been developed by F. J. Kallmann and D. Reisner (*J. Hered.*, 34, 293; 1943), with highly significant results. 616 twins, 930 sibs, 74 half-sibs and 668 parents in 308 complete families containing twins have been statistically analysed regarding the incidence of tuberculosis. The chance of contracting the disease increases in strict proportion to the degree of consanguinity to a tuberculous patient. The fact that monozygous twins exhibit 16 times as much similarity in resistance as compared with dizygous twins when all criteria are considered indicates that heredity, probably of a multifactorial nature, influences resistance. The authors point out that resistance to the invasion of the bacillus may be different from the factors of resistance to the spread of the established disease. This is supported by the fact that while there is a difference of 1 : 16 between resistance to progressive disease, there is only a difference of 1 : 3·5 in resistance to any form of clinical tuberculosis in monozygous and dizygous twins. The authors are proceeding further with this important analysis.

## Freshwater Bryozoa

MARY D. ROGICK, in her "Studies of Fresh-water Bryozoa. XIV. The Occurrence of *Stolella indica* in North America" (*Ann. New York Acad. Sci.*, **45**; 1943), records *Stolella indica* Annandale from North America for the first time. The genus was known hitherto only from Asia and South America. This freshwater bryozoon was collected in a pond in Westtown, Chester County, Pennsylvania, where it was fairly abundant on submerged twigs. The pond is fed from a spring passing through a meadow and contains much submerged pond-weed and some lily pads. Filamentous algæ were abundant on the submerged twigs, logs and other objects. In a larger pond nearby, four other species of freshwater Bryozoa occurred. A note on statoblasts in general suggests a simplification in nomenclature, and the terms floatoblasts, sessoblasts and spinoblasts are used for floating, sessile and spiny statoblasts respectively.

## Biotin Content of Enzymes

AMONG the members of the vitamin B complex, thiamin, riboflavin, and nicotinic acid occur in combination with a protein, that is, as the prosthetic groups of enzymes involved in respiration. The other members have been assigned no definite role in cellular metabolism. Several of these, notably biotin and *para*-aminobenzoic acid, occur in tissue in a bound form and are liberated only on strong hydrolysis. It might be expected that they also function as prosthetic groups of enzymes. D. R. Miller, J. O. Lampen and W. H. Peterson (*J. Amer. Chem. Soc.*, 65, 2369; 1943) find, however, that the biotin and *para*-aminobenzoic acid contents of six crystalline and three non-crystalline enzyme preparations, and one crystalline protein not an enzyme, lead to minimum molecular weights far in excess of the figures assigned to these enzymes. It is assumed, therefore, that the biotin and the acid are more probably contained as impurities in the crystalline proteins rather than forming an integral part of the enzyme.

## Physiology of Pollen

D. LEWIS (*J. Genetics*, 45, 117 and 261; 1943–44) has published further results of his work on the physiology of pollen, which is having far-reaching scientific as well as practical results. He shows that autotetraploidy weakens the inhibition of incompatible pollen. By suitable crosses in synthetic polyploids of *Oenothera organensis*, he has shown that the reduction of the inhibition is due solely to the diploidy of the pollen and not to the tetraploidy of the style. Pollen grains with two different *S* allelomorphs have been used on styles with one or both genes. In some cases there was a difference in compatibility, in others the result was indifferent. These results are considered in relation to the hypothesis that the *S* allelomorphs are competing for an antigenic substance similar to the antigen-antibody reaction in animals. Among many details of importance the author indicates that the effect of one *S* allelomorph of one pollen grain may sometimes be influenced by an association with another *S* allelomorph before pollen-grain formation. In the second paper, the author shows how the discovery of the weakened inhibition to diploid pollen may be used in the production of useful polyploid economic plants. By treating the pollen-mother cells with heat shocks, pollen grains with the unreduced number of chromosomes may be produced. If these pollen grains are heterozygous for the *S* allelomorphs, they will function on a diploid style, whereas the haploid pollen grain will be inhibited by the normal incompatible mechanism. By this method, triploid pears have been produced, and results in plums, cherries and apples indicate that much use should be made of Lewis's method in the future.

## Inheritance of Tristyly in *Lythrum Salicaria*

THE historic work of C. Darwin and Lady Barlow upon the inheritance of long-, mid- and short-styled plants of the loosestrife raised several unsolved problems. East published a hypothesis of lethal mid-genes to attempt to explain the results of crossing. This hypothesis left a number of unaccounted exceptions. R. A. Fisher and K. Mather (*Ann. Eugenics*, 12, 1; 1943) have followed their letter in *Nature* (150, 430; 1942) on this subject with extended results. They show that East's theory that the mid-gene was lethal when homozygous is wrong. By special methods of open pollination and statistics they have analysed large progenies and infer that the inheritance of long, mid and short is polysomic in type. Whether the inheritance is tetrasomic or hexasomic is unknown, but experiments are in progress. The authors have grown an open-pollinated population at Chelsea Physic Garden, and find that the mids have reduced fertility both in seed and pollen. This is different from that discovered by Darwin, and they suggest, therefore, that the experiment might be repeated at Down House, where the original work was performed.

## Iron Hill Igneous Complex, Colorado

THE detailed report by E. S. Larsen on the rocks and minerals of the Iron Hill stock in south-west Colorado (*U.S. Geol. Surv., Prof. Paper* 197 A; 1942) is an important and long-awaited contribution to descriptive petrology. The stock has an area of

twelve square miles; it is emplaced in Pre-Cambrian granites and is overlain by late Jurassic sandstones. The sequence of rocks in the complex is as follows: (*a*) A mass of dolomitic marble which forms an isolated hill a mile across, as well as several small inclusions within the later rocks. From the evidence of bodies of similar marble in the neighbourhood it is believed that the main mass is of hydrothermal origin, though it may have been intruded as a carbonate magma. (*b*) A coarse-grained melilite rock known as uncompahgrite. (*c*) A pyroxenitic suite which makes up about 70 per cent of the area and ranges from diopside-rock to types composed of biotite, perovskite-magnetite and apatite-perovskite, with varieties containing felspar, nepheline and sphene. (*d*) Ijolite composed of pyroxene, garnet and nepheline. In places nepheline appears to have 'soaked' into the pyroxenites. (*e*) Soda-syenite, commonly banded and associated with (*f*) a later nepheline-syenite; both (*e*) and (*f*) tend to occur near the borders of the stock. (*g*) A series of dykes of either nepheline-gabbro or quartz-gabbro, or in some cases both. Hydrothermal solutions were active throughout the history of the stock. To explain the origin of the complex the author postulates crystal differentiation of a basaltic magma modified by assimilation of marble in depth, but he himself points out one serious weakness in this conventional hypothesis, namely, its failure to account for the very high $TiO_2$ and $P_2O_5$ which characterize most of the rocks.

### Magnetic Susceptibility of Iron Tetracarbonyl

IRON tetracarbonyl, which has a molecular weight roughly corresponding with the formula $[Fe(CO)_4]_3$ is, like the other metal carbonyls, diamagnetic. The susceptibility values reported vary rather widely, and the value has been redetermined by H. G. Cutforth and P. W. Selwood (*J. Amer. Chem. Soc.*, 65, 2414; 1943). A well-crystallized material was prepared by way of the carbonyl $Fe_2(CO)_9$ from $Fe(CO)_5$. The actual material was found to be paramagnetic, suggesting para- or ferro-magnetic impurities. Measurements over a range of field strength showed that the susceptibility depended on the field. By plotting susceptibility against the reciprocal of field strength, extrapolating to infinite field strength gave a susceptibility of $-0{\cdot}07 \times 10^{-6}$, which is of the order expected, though rather small.

### Electric Arc between Solid Carbons and Graphite Electrodes

IN a paper by J. T. MacGregor-Morris (*J. Inst. Elec. Eng.*, 91, Pt. 1, No. 41; May 1944) entitled "Experiments on the Candle-Power and Brightness of the Positive Crater of the Electric Arc, using Solid Carbons and Graphite Electrodes", a critical examination is made of the ways in which a standard of high-intensity light could be developed using the positive crater of an electric arc between carbon electrodes in air, and an account is given of much hitherto unpublished experimental work bearing on this problem. A three-electrode arc was adopted in the researches, and a physical photometer was used in which a galvanometer deflexion automatically gave a measure of the light output of the arc. The accuracy of the method exceeds that possible with visual photometry, and rapid variations of candle-power can be observed. Graphite electrodes and a wide range of uncored soot electrodes were used. For a standard, either the candle-power of the positive crater measured along the axis of the anode might be used, or the brightness of a small portion of the crater near the centre. Measurements are given of the effect on candle-power and brightness of many factors including diameter, resistivity and purity of the anode, arc current, negative electrodes, atmospheric pressure and absorption due to arc flame. Special attention is given to the elimination of a phenomenon the existence of which is generally not obvious, namely, the rapid rotation of the arc stream, which is accompanied by a reduction of candle-power and brightness of uncertain amount. A critical comparison is made with other published work, especially work in other countries, and it is concluded that a standard can best be developed utilizing brightness, an accuracy of 1 per cent being so far attained.

### The Starch-Iodine Complex

THE nature of the blue material formed by the action of iodine on starch has been much discussed. In a series of papers by R. E. Rundle and co-workers (*J. Amer. Chem. Soc.*, 65, 554, 558, 1707, 2200; 1943; 66, 111, 130; 1944) evidence is presented for the view that the starch molecules are helical chains with a helix diameter of about 13·7 A., a length per turn of about 8 A., and about six glucose residues per turn, and in the starch-iodine complex the iodine molecules occupy the interior of the helices. Absorption spectra are said to confirm the existence of amylose and amylopectin as two components in whole starch. The amount of iodine bound in complex formation with amylose increases as the concentration of iodide decreases, becoming one iodine molecule for six glucose residues for infinitely dilute iodide solutions.

### New Methods in Stellar Dynamics

S. CHANDRASEKHAR (*Ann. New York Acad. Sci.*, 45, Art. 3, 131; 1943) has prepared an abridged version of new methods developed by him for the investigation of the dynamics of stellar systems. An outline of the general principles of a statistical theory of stellar dynamics is provided in the paper. An interesting point is mentioned in dealing with the statistics of a gravitational field which arises from a random distribution of stars. The acceleration which a star suffers during a certain interval can be formally expressed as the sum of two terms: (1) a systematic term due to the action of the gravitational field of the smoothed out distribution; (2) a stochastic term representing the influence of the near neighbours. There is a similarity between the problem presented by stellar dynamics, as stated in the above fashion, and the problems which occur in the modern theories of Brownian motion. Part 3 of the paper deals with the rate of escape of stars from clusters and the evidence for the operation of dynamical friction; the Pleiades cluster is considered in relation to the results obtained. When dynamical friction is ignored, a half-life for the Pleiades of $5 \times 10^7$ years is predicted; but if it is taken into consideration, the half-life is $3 \times 10^9$ years, and there is little doubt but that dynamical friction provides the principal mechanism for the continued existence of the galactic clusters like the Pleiades for times of the order $3 \times 10^9$ years. Allowing for dynamical friction, however, will not account for half-lives of the order $10^{10}$ years for such clusters, and this provides support for the now currently adopted 'short time-scale' of the order $3 \times 10^9$ years.

# APPLICATIONS OF SPECTROSCOPY

A CONFERENCE on the applications of spectroscopy to industrial and other problems was held, under the auspices of the London and Home Counties Branch of the Institute of Physics, at the Imperial College of Science and Technology on July 1; Dr. S. Whitehead presided.

The introductory address was given by Prof. H. Dingle, of the Imperial College, who opened with a short historical account of the development of spectroscopy. The pioneer work of Newton and, later, Fraunhofer, found no immediate practical application, and it was not until the middle of the nineteenth century that the subject began to acquire a general significance. Under the name of spectrum analysis, it was then regarded as a department of chemistry, and its discovery of new elements, coupled with the realization that a new and rapid method of chemical analysis had become possible, aroused hopes that a process of great practical value had been brought to light. These hopes were quenched, however, by the apparent capriciousness of the method, arising from causes which, in the existing state of physical and chemical knowledge, it was impossible to understand, and chemists soon abandoned it almost entirely. For the next few decades spectroscopy was kept alive, and in some degree developed, by astronomers, for whom no other means of astrophysical investigation was available, and in spite of some unavoidable errors, their contribution was an essential preliminary to the great revival which came with Bohr's theory of the hydrogen atom in 1913. For some dozen years thereafter, spectroscopy stood in the forefront of atomic physics, and the picture of the outer structure of atoms which eventually emerged was constructed *pari passu* with the explanation of the successive details of spectra.

This work, so far as atoms are concerned, is now almost complete, and one of its consequences is the rebirth of *applied* spectroscopy. Two main causes have been responsible for this. First, the requirements of physicists, in their enthusiasm to penetrate the secrets of atomic structure, impelled scientific instrument makers to turn their attention to the mass production of spectrographic apparatus, and this is now available in large quantity. Secondly, the newly acquired knowledge of the processes of production of spectra has made it possible to understand the vagaries which alienated the interest of earlier workers, and the spectrum has become a safe index to both the chemical composition and physical condition of the source of light. Prof. Dingle stated that the problem of qualitative spectrum analysis can now be regarded as solved; but considerable experience—not always possessed by the authors of published analyses—is necessary for trustworthy results. No general process of quantitative spectrum analysis, however, has so far been devised, although in certain special problems the method has been successfully used. He presented an analysis showing the various factors contributing to the strength of a photographed spectrum line, and described work which has been done at the Imperial College—and will be resumed as soon as conditions allow—directed towards the control of all of them except the amount of the corresponding element in the mixture to be analysed. The work of Mr. E. W. Foster, already published*, will, it is hoped, provide a basis for a process of quantitative spectrum analysis of great generality.

* *Proc. Phys. Soc.*, **53**, 594 (1941).

Mr. F. Twyman, managing director of Messrs. Adam Hilger, Ltd., followed with a description of certain spectroscopic instruments now available. He confined his remarks chiefly to those which seem of most immediate importance—namely, instruments for analysis by emission spectra and those for identification and estimation of liquids or vapours by absorption in the visible, ultra-violet and infra-red regions. The number of spectrographic analyses of minerals and alloys in Great Britain alone must run into millions every year, while absorption spectra, particularly in the infra-red, have lately assumed great importance in problems of molecular structure of interest to the biochemist and the industrial chemist. The commonest instrument for the production of emission spectra is still the quartz spectrograph; but gratings, largely through the advocacy of G. R. Harrison in America, have recently come into more general use, and experience must decide which is to be preferred for practical purposes. In quantitative work an estimate of the strength of spectrum lines must be made, and for this purpose microphotometers, or micro-densitometers, are available. Attempts have been made to measure intensities directly by photo-electric cells, but there is little doubt that for a long time to come the spectrum will be recorded photographically and the strength of the lines measured by the blackening of the plate. Mr. Twyman next discussed improvements in sparking circuits, and concluded his remarks on instruments for emission spectra by a brief reference to the identification of chemical compounds by X-ray crystal analysis.

The most characteristic feature of apparatus for absorption spectra in the visible and ultra-violet regions is the photometric device, of which the first example was the sector spectro-photometer. The principle of this instrument is common to all subsequent photographic spectro-photometers, except very recent ones still in the experimental stage; but certain improvements in detail have been introduced, which are exemplified in the Spekker photo-electric absorptiometer. In the infra-red, where absorption spectra give important information bearing on the structure of organic molecules, the original Hilger instrument designed in 1909 is, with a few improvements, still in use to-day. Prisms of quartz, fluorite, rock-salt and sylvine are available, making investigation of the infra-red region possible up to at least 21 $\mu$. The radiation is detected by a thermopile, and a recording form of the instrument has been devised.

The next speaker was Mr. D. M. Smith, of the Research Department of the British Non-Ferrous Metals Research Association. He discussed chiefly the difficulties met with in the spectrographic analysis of non-ferrous metals and alloys. In this work the chief problem is the quantitative determination of traces of impurities, and the methods adopted usually involve microphotometric measurements of arc and spark spectrograms, especially the latter. Important sources of error lie in the lack of precise specification of sparking conditions, lack of complete understanding of the effect of small differences between the samples to be analysed and those used to provide standards for comparison, and uncertainties in plate calibration arising from imperfect design in certain types of microphotometer. The British Non-Ferrous Metals Research Association has for some time been collaborating with its members in attempting to improve the accuracy of spectrographic methods, four panels of the Research Sub-Committee having been formed.

In addition to reports from the Photographic, Aluminium and Lead panels (the fourth panel deals with problems common to all the methods), further papers on specific applications are shortly to be published in book form under the title "Collected Papers on Metallurgical Analysis by the Spectrograph".

It is generally agreed that the standard alloys used for comparison should be closely similar in bulk composition and metallurgical history to the samples for analysis, and some pre-sparking is generally regarded as desirable in non-ferrous analysis, although in the analysis of steels it appears to be unnecessary. The 'direct comparison' method, due to A. Walsh, in which no internal standards are used, has proved successful in certain problems, but it is very susceptible to errors from incomplete control of the spark discharge. The reproducibility of spectrographic determinations is most concisely expressed by the standard deviation derived from an adequate number of repeat tests on the same sample, although the calibration of the plate by the use of standard alloys is a possible source of systematic error. In general, methods of compensation, based either on empirical relationships or on considerations of source temperature, are less satisfactory than improvements in the source of excitation as regards increasing analytical accuracy.

Dr. W. A. Roach, of the East Malling Research Station, then addressed the Conference on applications of spectroscopy to biological problems. Lundegardh (1928) and Ramage (1929), he said, were two of the earliest workers to use emission spectroscopy for studying the biological importance of minerals. Ramage burnt the dried and powdered material, rolled in a filter paper, in front of the slit of a spectrograph. Lundegardh sprayed a solution of the ash into an oxy-coal gas flame. The arc method has been used by Webb and Fearon (1937) to make a survey of elements occurring in living tissues, and by Lewis, who found that serious trouble in young animals on 'teart' pastures in the west of England was caused by an excess of molybdenum. Mitchell used Goldschmidt's cathode layer method of soil analysis for studying a serious trouble in sheep called 'pining', which was traced to a deficiency of cobalt. These and absorptiometer methods are now in routine use in a number of biological laboratories.

Similar methods, as well as others, are being used at the East Malling Research Station for the diagnosis of mineral deficiencies and excesses in plants. The limitations of plant analysis when employed alone are illustrated by facts first discovered by Passy (1910) when seeking the cause of widespread chlorosis (absence of chlorophyll) in an orchard. The trouble was cured by injecting an iron salt into the chlorotic trees; yet the percentage content of iron was highest in chlorotic foliage, lower in certain green branches and trees found in the orchard, and lowest in the trees injected with iron salt. The iron in the chlorotic leaves must have been in a form useless to the plant. When iron in a useful form was injected, the leaves grew in proportion to the injected iron, which 'diluted' the useless iron obtained naturally. This type of faulty mineral uptake is known as 'lime-induced chlorosis', since it is common on soils containing excess of calcium carbonate.

A system of diagnosis is being built up by studying the mineral composition of plants in relation to their performance, supplemented when necessary by testing how far performance is improved by injecting more of any selected element into the plant. Healthy plants tend to have a characteristic composition, and a deficiency of any essential element can be diagnosed by analysis alone. When calcium occurs in excess, however, the normal content of any of the trace elements (iron, manganese, zinc, boron, copper, etc.) may prove inadequate because it may be in a state useless to the plant. Supplementary methods, such as plant injection and a study of plant symptoms which are often characteristic of mineral deficiencies, must then be employed.

The final address was given by Dr. R. W. B. Pearse, of the Imperial College, who spoke on applications of the band spectra of molecules. These fall into two classes: first, those in which direct use is made of the spectrum, and secondly, those in which the spectrum is analysed in order to determine the structure of the corresponding molecule. In applications of the first class, a band system, and not an individual band, is to be taken as the molecular analogue of a single line in the spectrum of an atom. By means of such systems the scope of analysis can be extended in several ways. Thus, inaccessible sources of light, such as comets for example, sometimes show the presence of many of their constituents by bands and not lines. Secondly, certain elements which give no line spectra in the ordinary regions of observation when subjected to arc or spark conditions readily show bands if suitable elements are present with which they can combine. Thus, fluorine and chlorine can often be detected by bands of $CaF$ and $CuCl$; nitrogen and oxygen in the atmosphere of a copper arc show a spectrum of $NO$; and the spectrum of a hydrogen flame shows $S_2$ bands when sulphur is present. Thirdly, glow discharges in vacuum tubes often show bands which indicate the nature and purity of the gases present, and give a clue to the origin of unwanted residual gases, for example, leakage from the air, presence of moisture, degassing of walls, decomposition of grease, etc. Fourthly, absorption spectra have enabled certain complex molecules to be identified, and indicated changes in the constitution of such molecules by corresponding changes in the spectrum. Tables of data are now available for the identification of molecular spectra, and their use could be greatly extended.

Applications of the second class require a much more detailed study of the spectrum. The spectra of diatomic molecules can be analysed into bands and branches, and energy-level diagrams constructed. Molecular constants representing the levels give the separation of the constituent atoms, the moment of inertia of the molecule, its frequency of vibration and electronic energy in various states, and the law of force between the atoms. If the observations are sufficiently extensive, the energies of dissociation for the various states can be obtained. This knowledge can be used, with the co-operation of the mathematician and the physical chemist, to throw light on many chemical problems. The determination of temperature and detection of isotopes are further possible products of the analysis of molecular spectra.

A short discussion was held at the conclusion of the meeting, at which it was proposed by Dr. J. Convey, and seconded by Dr. H. Lowery, that in view of the great importance which applied spectroscopy has acquired in various fields, the Board of the Institute of Physics should be asked to arrange for the formation of a group for the study of the subject. The proposal met with general agreement, and is to be submitted to the Board.

# CONTROL OF CROSS-INFECTION BY BACTERIA

THE Medical Research Council's War Memorandum, No. 11, entitled "The Control of Cross-Infection in Hospitals" (London: H.M. Stationery Office, 1944. 6*d*. net) epitomizes a great deal of research on this important question. Cross-infection, says Sir Wilson Jameson in his introduction, is most apparent and dangerous among infantile and juvenile patients in hospitals, so that this memorandum deals mainly with the risks in children's wards; but it is pointed out that the risks exist also among children at home and wherever else they assemble. Nor are adults by any means free from them. The risks are naturally greatest where infectious diseases are being treated, but they exist in every hospital ward; and, when a cross-infection occurs, the cost of it may be so high that any measures taken to prevent it are in the long run economical, even if these include, as they often must, building alterations.

The commonest types of cross-infection are the respiratory ones, such as tonsillitis, middle ear disease, 'colds in the head' and pneumonia. "If tonsillitis due to hæmolytic streptococci is accompanied by a rash, it is known as scarlet fever." Some thirty serological types of hæmolytic streptococci have been identified, and one and the same type may cause different effects in different patients. The tracking down of these types may be a very complex undertaking. Diphtheria, measles, chicken-pox, whooping cough, German measles, mumps and that disease about which much has been written recently, infective hepatitis, are other important infections which gain entrance by the respiratory tract. Gastro-intestinal infection may be a serious cause of death among infants in hospital. Epidemic diarrhœa, bacillary dysentery and diseases of the typhoid group may also occur. Wounds and burns may become infected, and abscesses, erysipelas, cellulitis and septicæmia may follow. Hæmolytic streptococci and staphylococci are the commonest causes of cross-infection of wounds. There are also the skin infections, impetigo, ringworm, scabies and pediculosis and infections of infants which may cause inflammations of the mother's breast. Nor should we concentrate all our attention on cross-infection of the patients. The nurses and other personnel need protection from it. Dr. Joyce Wright (*Brit. Med. J.*, 585, April 29, 1944), in her study of the sickness records of nurses in University College Hospital between 1936 and 1938, discusses this problem and emphasizes the need for further work on it. Although smallpox is outside the scope of the Medical Research Council's memorandum, it is interesting to note in passing that the theory that smallpox may spread from smallpox hospitals to the surrounding population by way of the air has been revived and supported by Dr. C. K. Millard (*Brit. Med. J.*, 629, May 6, 1944).

Infection in a hospital may be either from a clinical case, from a case which has not been recognized or is in its incubation period, or from a 'carrier' who is either a convalescent or harbours the organisms concerned without showing any symptoms. From any or all of these, infection spreads by way of the secretions or discharges or from the skin or from wounds. It can spread by contact with the patient or with his clothes or belongings, or by means of food or living vectors. But of special interest nowadays are infection by dust and by droplets of moisture, which can be projected 3–6 ft. through the air by talking, coughing or sneezing. Such infection may fall either on another person or on to bedclothes, utensils, food or on to the floor. Small droplets may evaporate and leave in the air minute droplet nuclei which are infected and may carry infection for considerable distances. The diagrams printed in this memorandum indicate that bacterial counts of the air show considerable increases when bed-making or floor-sweeping raises the dust. Dry floor-sweeping does this especially, and the dust settles on bedclothes, on the furniture, on food, toys, utensils, and so on. Pathogenic bacteria can live in floor dust for weeks or even months, and may be numerous there. Large numbers of virulent diphtheria bacilli have been isolated from the floor dust of diphtheria wards. It has been estimated that the floor sweepings of one ward in an ear, throat and nose hospital contained 100 million hæmolytic streptococci; and tubercle bacilli and pneumococci have also been obtained from floor dust. The bacteria of ward dust come mainly from bedclothes; and even the straightening of the clothes of one bed can raise the bacterial count of the surrounding air 100 times. The scales of skin, and hair and finger-nail cuttings found in dust also may carry pathogenic bacteria.

Surrounded by this multitude of enemies, what are we to do? War Memorandum No. 11 referred to above gives detailed directions. Among administrative measures are the abolition of the large open ward and encouragement of the modern tendency to build smaller units. About half the beds in a children's hospital should be in small isolated rooms, so that patients may be isolated if necessary, and so that those suffering from the same disease can be grouped in small wards. Patients should be grouped according to medical risks rather than according to age. Nurses' duties should be so allocated that risks of cross-infection are avoided. This applies especially to those engaged in the kitchens, on the preparation of feeding bottles or on toilet duties. Nurses should receive training in the risks of cross-infection and in hygiene and bacteriology. Similar rules should apply to visitors and to walking patients who may be helping the staff. Immunization and chemo-prophylaxis are also helpful. Labour-saving methods are also discussed. The use of trolleys, for example, in the serving of meals considerably reduced the 7½ miles walked by the staff of one hospital when they served one meal. The control of contact infection is discussed under the headings, handwashing, laundry, cleanliness of kitchens and food stores, the reduction of flies and other insect pests and, in children's hospitals, breast and artificial feeding.

The control of droplet infection is effected by adequate ventilation at all times and all the year round, by placing beds not less than 12 ft. apart, by the use of efficient face masks (which should not be carried in pockets and should only be used once), by the use of antiseptic aerosols insufflated into the air. R. J. V. Pulvertaft (*J. Hyg., Camb.*, **43**, 352; 1944) gives a valuable summary of recent work on these aerosols, and the same journal contains in earlier issues other accounts of research done on them. Prof. S. Mudd, of the University of Pennsylvania, has given us recently (*Brit. Med. J.*, 67, July 15, 1944) an American view of progress in the sterilization of the air. Ultra-violet irradiation is also helpful. Prof. L. P. Garrod (*Brit. Med. J.*, 245, Feb. 19, 1944) claims that his study of hospital dust shows that "ordinary, diffuse daylight even on a cloudy day and

even in winter in England, can be lethal to bacteria, and that glass is no absolute bar to this effect".

Dust-borne infection has received much attention recently. The interesting work quoted in this War Memorandum No. 11 shows that bedclothes should be handled gently and should not be allowed to touch the floor. The number of bacteria scattered from them is much reduced if they are impregnated with 'technical white oil'. Similarly, the treatment of wooden and linoleum-covered floors with spindle oil reduces the risk of scattering bacteria during sweeping. A striking diagram of results of bacterial counts of the air before and after oiling of floors illustrates this. Floors made of rubber, concrete or composition should be washed, vacuum-cleaned or sprinkled with damp sawdust before sweeping. For the same reasons dusting with dry dusters is banned. Food, sterile materials and so on should, of course, be protected from dust, and any article which falls on to the floor should be regarded as being contaminated. A recent paper by F. C. Harwood, J. Powney and C. W. Edwards, of the British Launderers' Association Laboratories (*Brit. Med. J.*, 615, May 6, 1944) describes a new technique for oiling bedclothes which incorporates the use of dilute water-in-oil emulsions. P. H. R. Anderson, J. A. Buchanan and J. J. MacPartland, in the same issue of that journal (p. 616), record their successful lowering of the rate of respiratory infections in a military barracks by the oiling of the floors with spindle oil. Joyce Wright, R. Cruickshank and W. Gunn, in the same issue (p. 611), have shown that oiling of the floors would not by itself be enough to control the spread of dust-borne hæmolytic streptococci in measles wards, but that oiling of all the bedclothes in addition to oiling of the floors did control this. The infection cycle is, they say, respiratory tract—droplets and discharges—bedclothes and garments—ward air during bed-making—ward dust—ward air during sweeping. Oiling floors thus attacks only the final links in this cycle, and oiling of the bedclothes and linen attacks the earlier ones.

The Medical Research Council memorandum gives in its appendixes lists of disinfectants and instructions for their use and rules for sterilization, isolation, and the application of dressings. The special requirements of maternity wards are also considered, and rules are given for the procedure to be followed when an infection does occur in a ward. G. LAPAGE.

## SAP-STAINS OF WOOD

SCHEFFER and Lindgren[1] present a summary of approximately ten years of field and laboratory work on sap-stains of wood. They state that market demands for wood products are becoming more exacting, making stained wood more difficult to dispose of. Losses from degradation are in general decreasing because of improved methods in controlling stain. Chemical, mechanical, and fungus stains are described and discussed as to symptoms, cause, timber species involved, effect on various wood properties, and control, the major emphasis being on blue stains caused by fungi. In the United States blue sap stains are of greater importance in the south than in any other region, although locally and seasonally important also on the west coast and in northern Idaho and contiguous regions. The chief factors influencing the development of fungus blue stains in sapwood lumber and other wood products are temperature, oxygen, and water. No correlation was found between wood density and susceptibility to stain. Flat-grained lumber was slightly more susceptible to stain than edge-grained, due to the greater number of rays exposed and the larger proportion of sapwood. Wood once seasoned and remoistened was less susceptible than unseasoned wood, but not significantly so. No difference was found in susceptibility to stain between winter-cut and summer-cut timber.

The fungi causing blue stain are disseminated by air, ips beetles, mites and possibly to some extent by the saws which cut the logs into lumber. Toughness (ability to stand loads applied quickly) of stained wood was significantly reduced as compared with unstained wood; but other mechanical properties were not significantly affected. Creosote under pressure penetrated considerably deeper into stained pine bolts than into matched unstained bolts. The presence of stain did not affect the yield or strength of paper made from the wood, nor did it affect the glueing and other properties of the wood. The commercial aspects of stain control in the southern United States are discussed, including the advantages and disadvantages of end-racking, end-piling, crib-piling, steaming, kiln drying, and chemical treatments. The chemicals most used at present are 'Lignasan' (ethyl mercury chloride plus inerts), 'Dowicide P.' (mixture in equal parts of sodium tetrachlorophenolate and sodium 2-chloro-o-phenylphenolate plus excess alkali) and 'Dowicide H.' (sodium tetrachlorophenolate plus excess alkali). The phenolates are more persistent on the lumber and more toxic to moulds. In poor seasoning weather, the control sometimes is erratic. It is estimated that three billion feet of pine and hardwood lumber was dipped or sprayed in 1936. Not only lumber but also other products, such as posts, barrel staves, shingles, lath, and exterior millwork now are treated to control stain.

One of the problems of commercial stain control is that treatments generally successful in preventing the development of sap-stain in lumber occasionally fail. As one of the basic approaches to the solution of this problem, Verrall[2] studied the relative importance and seasonal prevalence of wood-staining fungi in the southern United States. The studies were made in 1937 and 1938 in Louisiana, Mississippi, and Georgia. More than a thousand isolations were made from both logs and lumber of twelve species of trees, among which long-leaf pine (*Pinus palustris* Mill) and red gum (*Liquidambar styraciflua* L.) predominated. Blocks were inoculated with the isolated fungi to test their staining ability. The staining floras of both logs and lumber were very nearly alike. Those most important in pines were: *Ceratostomella pilifera*, *C. ips*, *Diplodia natalensis*, and other *D.* sp.; on hardwoods, *Endoconidiophora coerulescens*, *Ceratostomella pluriannulata*, *Diplodia natalensis*, and *Graphium rigidum*. *Diplodia natalensis* is of prime importance only in the summer months, *Endoconidiophora coerulescens* is of low incidence in the summer months, and *Ceratostomella pilifera* is relatively more frequent in winter than in summer, although of importance the year around. *C. ips*, *Diplodia sp.*, *C. pluriannulata* and Graphium fluctuate very little with season. *Diplodia natalensis* isolated from stained wood is identical with that isolated from cotton and other common agricultural plants in the region. Its prevalence in summer is thought to be due to a combination of ability to grow at high temperature, and

abundance of inoculum produced during this season on cotton and other plants.

Verrall[3] also identified the fungi associated with stain in green lumber treated with Lignasan and with Dowicide P. He found no special staining flora on the treated wood, and no evidence of a build-up of stains resistant to the treating chemicals. Some stain was obtained on most treated pieces of pine lumber under the severe conditions of the tests. *Endoconidiophora coerulescens* is probably the most important staining fungus on hardwoods, and treatments were less effective against this fungus than against other species. However, no difficulty was experienced in getting hardwood lumber to remain stain-free after treatment. *Graphium rigidum* and *Ceratostomella pluriannulata* were isolated in relatively greater numbers from Lignasan-treated than from Dowicide-treated wood. *Diplodia natalensis* was not isolated from treated wood. The greater part of the occasional severe staining of treated wood is attributed to poor handling practice, not to failure of the treatments themselves.

# FORTHCOMING EVENTS

## Tuesday, August 29

BRITISH PSYCHOLOGICAL SOCIETY (INDUSTRIAL SECTION) (at the National Institute of Industrial Psychology, Aldwych House, Aldwych, London, W.C.2), at 12.30 p.m.—Dr. K. J. W. Craik: "Proposed Work of the Medical Research Council's Unit of Applied Psychology at Cambridge".

# APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

READERSHIP IN PHYSICAL ANTHROPOLOGY—The Registrar, University Registry, Oxford (August 31).

SECRETARY to the Editorial Board of the 'Transactions' (must hold a Degree in Physics, Metallurgy or Engineering of a British University, or an equivalent technical qualification)—The Secretary, Institute of Welding, 2 Buckingham Palace Gardens, London, S.W.1 (August 31).

CHIEF ELECTRICAL ENGINEER AND MANAGER—The Town Clerk, Town Hall, Chichester (August 31).

PRINCIPAL ENGINEERING ASSISTANT on the permanent staff of the Buildings Department—The Clerk to the Kent County Council, County Hall, Maidstone (marked 'Principal Engineering Assistant') (August 31).

BOROUGH ELECTRICAL ENGINEER AND MANAGER—The Town Clerk, 4 Woodville Terrace, Gravesend, Kent (September 1).

ASSISTANT MASTER to teach BUILDING CONSTRUCTION, MATHEMATICS, TECHNICAL DRAWING AND MECHANICS at the Junior Building School, Cowes—The Director of Education, Education Offices, County Hall, Newport, I. of W. (September 1).

LECTURERS (two, full-time) IN PHYSICS—The Clerk to the Governors, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham, Essex (September 2).

UNIVERSITY CHAIR OF STATISTICS tenable at the London School of Economics—The Academic Registrar, University of London, South Kensington, London, S.W.7 (September 4).

CHIEF STEAM TURBINE DESIGNER for a firm in the Midlands—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2249.XA) (September 4).

GRADUATE ASSISTANT (full-time, temporary) to teach MATHEMATICS AND SCIENCE—The Principal, Twickenham Technical College, Egerton Road, Twickenham, Middx. (September 5).

ASSISTANT LECTURER IN ZOOLOGY, and a DEMONSTRATOR IN ZOOLOGY—The Acting Registrar, The University, Leeds 2 (September 8).

ADVISORY OFFICER IN THE ECONOMICS DEPARTMENT—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow (September 8).

CURATOR OF THE CITY MUSEUMS—The Town Clerk, Room 57, Civic Hall, Leeds 1 (endorsed 'Curator of the City Museums') (September 9).

LECTURER (full-time) IN BIOLOGY, and HEAD OF THE SCHOOL OF CHEMISTRY—The Principal, Leicester College of Technology and Commerce, Leicester (September 9).

ENGINEER (Water Supplies) by the Gold Coast Government Public Works Department—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. E.1094.A) (September 11).

DIRECTOR OF THE BRITISH NON-FERROUS METALS RESEARCH ASSOCIATION—The Chairman of Council, British Non-Ferrous Metals Research Association, Euston Street, London, N.W.1 (marked 'Personal') (September 15).

ASSISTANT DAIRY BACTERIOLOGIST (temporary)—The Registrar The University, Leeds (September 15).

BOROUGH ENGINEER AND SURVEYOR—The Town Clerk, Town Hall, Walworth Road, London, S.E.17 (endorsed 'Borough Engineer and Surveyor') (September 22).

LECTURER IN VERTEBRATE ZOOLOGY—The Secretary, The University, Edinburgh (September 25).

CHAIR OF ELECTRICAL ENGINEERING—The Acting Registrar, The University, Leeds 2 (September 30).

CHAIR OF BIOLOGY in Victoria University College, Wellington, New Zealand—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, London, W.C.1 (September 30).

PRINCIPAL OF THE HACKNEY TECHNICAL INSTITUTE, and PRINCIPAL OF THE SOUTH-EAST LONDON TECHNICAL INSTITUTE—The Education Officer (T.1), County Hall, Westminster Bridge, London, S.E.1 (September 30).

PROFESSOR OF PHYSICS—The Registrar, University College, Singleton Park, Swansea (October 18).

LIBRARIAN—The Librarian, Queen's University, Belfast (October 31).

CHAIR OF PSYCHOLOGY in the University of Sydney—The Secretary, Universities Bureau of the British Empire, c/o University College Gower Street, London, W.C.1 (October 31).

TECHNICAL ASSISTANT (female, non-resident) for Clinical Laboratory Work—The General Superintendent, Royal Infirmary, Manchester.

TEACHER mainly for MATHEMATICS AND ENGINEERING SCIENCE in the Junior Technical School and in Senior Day and Evening Classes—The Principal, County Technical College, Gainsborough, Lincs.

LECTURER IN ELECTRICAL ENGINEERING with special reference to Design of Electrical Machinery—The Principal, Faraday House Electrical Engineering College, 62–70 Southampton Row, London, W.C.1.

TEACHER OF ENGINEERING DRAWING AND MECHANICS in the Junior Technical School for Boys—The Principal, Wimbledon Technical College, Gladstone Road, London, S.W.19.

TEACHER (full-time, temporary) OF MECHANICAL ENGINEERING SUBJECTS in the Technical College and Junior Technical School—The Principal, Technical College, Talbot Road, Stretford, Lancs.

DEMONSTRATOR IN ANATOMY—The Secretary, University College, Gower Street, London, W.C.1.

PRINCIPAL of Natal University College—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, London, W.C.1.

# SCIENTIFIC AND INDUSTRIAL RESEARCH.—II

WE have already noted that one of the first problems in the development of an adequate strategy of research is the re-examination of our whole educational system with respect to the provision of adequately trained and broadly educated workers for scientific research, and the balancing of the immense needs for technical and scientific training by competent education in the liberal arts and humane studies. This involves not merely an adequate supply of competent investigators, but also of those capable of directing research effectively, as well as of the laboratory technicians necessary for the efficient use of the fully trained research worker. Again, since both the support of research in the first instance, and the utilization of its results afterwards, involve some understanding by the community generally of the value and significance of scientific research, we are concerned also with the general education of the community and not merely with education at the university level.

This point has not yet been as fully appreciated by scientific workers as is desirable, despite the attention which has been focused on education in general by the Government White Paper on Educational Reconstruction, the debates leading up to the new Education Act, and the recent series of reports such as the McNair Report on Teachers and Youth Leaders, the Norwood Report on Curriculum and Examinations in Secondary Schools and the still more recent Fleming Report on the Public Schools and the General Educational System. This neglect is the more important as the attention given to scientific and technical training in the Government's own White Paper and the Norwood Report, to say the least, can scarcely be regarded as adequate. To some extent this has been corrected in the Statements issued by Nuffield College on "Industry and Education" and on "Problems of Scientific and Industrial Research", the latter of which reiterates that the foundations for a sound and scientifically minded industry must be laid in the schools by good grounding in mathematics and in the principles and methods of science, coupled with a thorough mastery of the English language and a broad cultural approach to all subjects. "We live in a world in which science lies at the very roots of community, and a mastery of scientific thinking grows more and more indispensable for the successful practice of the arts of life. The culture of the modern age, if it is to have any meaning, must be deeply imbued with scientific ways of thought."

Strong support for this point of view can be found in the report of the Chemistry Education Advisory Board on the Education and Training of Chemists, and in the report of the Federation of British Industries Committee on Industry and Education, but it is one that will demand the sustained support of scientific workers if it is to be achieved in practice. None the less, it is to the universities that we may well direct our attention in the first instance. Their place in the strategy of research, as the main source

of supply, both direct and indirect, of the type of personnel required, is unique and unchallengeable. It is this position that must be considered before we consider the further question of their place in, or relation to, whatever organization of research may be desirable to implement our strategy.

Attention has been directed to the universities as a source of supply for the research workers required in industry and elsewhere in several reports. While in most of these papers and reports the short-range and long-range problems are clearly distinguished, the more fundamental problems involved have seldom been discussed. The universities are social institutions, just as research from one point of view is a social process, and any scheme of university expansion with its concomitant calls for larger endowment must make plain to the ordinary citizen what social purposes such expansion will serve. That presupposes a re-examination of the fundamental questions of the functions of the universities and their place in the society of to-day. As Rashdell has pointed out, new needs must be met by new machinery. University institutions must undergo perpetual modification in the future, as they have undergone perpetual modification in the past.

But Rashdell's further observation in this connexion is worth noting. "It is well," he adds, "in this as in wider fields of social, political and religious organisations, as far as possible to preserve historical continuity." That observation is worth remembering for the help that attention to such historical continuity may give in developing a social philosophy. A false philosophy, as Dr. Conant recently noted, was one of the reasons for the triumph of Nazism in Germany; and the University Grants Committee in its last quinquennial report recognized the special responsibilities of British universities in this field in view of the suppression in European universities of independent thought and critical discussion. The late Prof. J. L. Stocks was even more explicit. "What is wanted," he wrote in an essay "On the Need for a Social Philosophy", "is a philosophic discipline, encouraging and promoting the careful exposition and discussion of the pre-suppositions of social organisation on every side. No such discipline exists in this country at present. Our generation is not being given in these matters the tools necessary for coming to a sound critical judgment, and . . . philosophy alone has the power to give them those tools. When men do not know the faith by which they live, they will be apt inadvertently to betray it."

In the attempt to restate the functions of the universities in the modern world, too little regard has been paid to the experience of the past. That can afford a surer guide to our grand strategy than preoccupation with the minor tactics required to deal with some transient if embarrassingly urgent problem. There could in fact be no finer starting point for the reconsideration of the place of the universities in the society of to-day than Rashdell's study of the medieval universities from which we have already quoted. "The two most essential functions which a true university has to perform and which all universities have more or less discharged amid the widest possible variety of system and method and organisation . . . are to make possible the life of study, whether for a few years or during a whole career, and to bring together during that period, face to face in living intercourse, teacher and teacher, teacher and student, student and student." Thus Rashdell has crystallized three of the four principles which guided the Association of University Teachers in its approach to university problems as set forth in the report on university developments: the pursuit of knowledge, not controlled or dominated by any private or corporate interest; the dissemination of knowledge and culture; and the communal aspect—universities are schools of communal living, in which the development of students as individuals and their development as social beings are equally important.

Those three principles are more or less explicit in the great bulk of the reports and books or papers that have discussed the problems of university development, whether in regard to research or teaching, in recent years. The fourth principle, that universities are a part of society, both materially and intellectually, and bear a direct responsibility, and must therefore study the application of organized knowledge to practical problems, and train men and women for particular tasks finds almost equally general acceptance.

It is of special interest, to the scientific worker, to note how well these ideas are brought out by Dr. F. R. Leavis in his sketch for an "English School" in "Education and the University". This plea for a liberal or humane school at first appears to be remote from their own concern, but Dr. Leavis has crystallized his objective in words which show unmistakably its relevance. Strongly contesting subjective views, he visualizes a university as a focus of humane consciousness where intelligence, bringing to bear a mature sense of values, applies itself to the problems of civilization. That is the reason for his plea for a school of the humanities. He aims at producing minds that will approach the problems of modern civilization with an understanding of their origins, a maturity of outlook, and a sense of human possibilities, difficult of achievement, that traditional cultures bear witness to and that it would be disastrous to lose sight of for good.

Whatever view we may take of the functions of the universities or of their place in our strategy of research, we cannot ignore their inherent possibilities of leadership. Just as in the field of thought a university stands for adventure, so in regard to society the university plays its greatest part as a stabilizing factor. Sir Walter Raleigh pointed out that a university must be perpetually alert to discard superseded methods and to detect the importance and significance of new studies and new ways of approach, encouraging adventure and giving to each a place in the long line of pioneers who are pushing forward the boundaries and claiming new provinces. While serving as a repository of the reasoning of the ablest minds attracted to it, the university must continue its vital function of checking the dangerous extremes to which all institutions with power are subject, and above all at this time those extreme

tendencies of modern civilization shown in the modern State and in the tyranny of opinion.

But if it is not part of the duty of a university to inculcate any particular philosophy of life, it is, as the University Grants Committee recognized, most assuredly an essential part of its work to assist its students to formulate adequate philosophies of life for themselves. Only so can the universities make their great contribution to meet the danger to which Prof. Stocks directs attention; and there is here a very important practical point to be considered in relation to demands for increasing the range of technological studies at the universities. In a passage that deserves to be noted particularly in regard to the extra-mural activities of the universities and their part in adult education, Rashdell, after a warning not to lose or lower the ideal of the university as the place *par excellence* for professed and properly trained students, not for amateurs or dilettantes or even for the most serious of leisure hour students; for the highest intellectual cultivation, and not merely for elementary instruction or useful knowledge; for the advancement of science, and not merely for its conservation or diffusion; continues with the plea that it is the place "where different branches of knowledge are brought into contact and harmonious combination with one another, and where education and research advance side by side".

Prof. D. W. Bronk pointed out in his paper on the discovery and interpretation of biological phenomena in the symposium on the "Organisation, Direction and Support of Research" arranged by the American Philosophical Society last November that the departmentalism of science has tended to become more restrictive and the boundaries of teaching departments have insensibly created artificial barriers to the free range of inquiry. Questions as to the barriers we have erected around disciplines and departments must be frankly faced in considering the replanning and reorganization of the universities to meet post-war needs. Nowhere will more fundamental thinking be required than at this point and nowhere more than here will the universities need, as has been well said, "official window cleaners whose chief function is perpetually to open windows and let in air—the colder the better".

But there is more involved here than decisions as to how far to retain some of these compartments for administrative convenience or the clear thinking about the impediments they offer to effect research and the limitations they impose on the character of the training we give our future investigators. As already indicated, we have to define the relation of technology to university studies. Technological studies have significance not only in regard to the survival of the nation and the needs of individuals, but also to the advancement and the unity of knowledge itself. In fact, technological requirements are an important factor enforcing the consideration of a new synthesis of scientific effort. Nevertheless, we are, as Mr. P. R. Morris rightly said in a recent lecture to the Royal Society of Arts, "in danger of forgetting, and the present haphazard organization of courses and studies encourages us to continue to forget, that the differentiation of knowledge into faculties and subjects can easily be regarded as a division of knowledge itself. There is here a fundamental question of principle of the highest importance and also a practical problem of systematisation and organisation".

That fundamental question has to be considered both from the point of view of the universities themselves and from that of their relations with the technical colleges and the place of the latter in the educational system. It is not the only principle which should determine whether or not the technical colleges should be developed into institutions of university rank but independent of the universities, but it is an important factor bearing on our decision. Almost a generation ago, Prof. Arthur Smithells argued powerfully that the isolation of professional or technological studies and their cultivation in separate institutions was fraught with serious dangers and disadvantages, and advocated the embodiment of professional and technical studies in our universities, and for the reason that a wider outlook would be thereby promoted. The Committee on Post-War University Education of the British Association, in its recent report though without reasons given, supports this view and considers that the development of technical colleges into institutions of university rank, but independent of the universities, should not be encouraged. Rather, British colleges carrying out technological work of university standard should be associated with their regional university, as the Imperial College of Science and Technology in London, the Royal Technical College in Glasgow and the College of Technology in Manchester.

From this view Sir Alfred Egerton dissents. He considers it highly important that there should be in Great Britain an institution such as the Imperial College, somewhat similar to the Massachusetts Institute of Technology; there should be one in the south of England, one in the north and one in Scotland, closely associated with the universities, with strong post-graduate schools and providing undergraduate teaching. There have been other powerful pleas for such institutes from the research point of view. But it is important that there should be no confusion with other proposals to advance certain university colleges to full university rank, which is a possibility also contemplated by the British Association Committee. Such proposals obviously are related primarily to the quantitative aspects of university expansion—the size of our university population and the size and number of the universities to cater for it.

These questions have been raised already, notably by Sir Ernest Simon in his pamphlet on the development of British Universities, and by the Association of University Teachers in the report already mentioned, where tentatively it is suggested that a university in Great Britain should range in size from 2,000 to 5,000 students, with residential accommodation for a large number of students. On this basis a national policy would first aim at building up the smaller universities to the optimum size and sub-

sequently at transforming some at least of the university colleges into true independent universities to provide the balance of whatever accommodation may be required to meet the needs of the university population at which it is decided to aim. Some approximate figure must clearly be adopted as target if any real plans for university expansion are to be formulated. That estimate will depend in part only on the demands for research workers and for teachers, for it must be related to the general question of university finance and the distribution of what increased grants may be available, not merely for expansion but also for improving the conditions and standards in existing departments. In fact, until we have attempted to formulate some reasonable estimate as to the student population at which we should aim, whether the pre-war standard of about 50,000, with better selection and higher standards, a twenty per cent increase, the fifty per cent increase suggested by the Association of University Teachers, or a hundred per cent increase, we can scarcely decide on what increase in grants is desirable, and this is a notable omission in the report of the British Association Committee.

It will be recognized, of course, that closer co-operation between the universities, particularly in regard to the development of schools of research and teaching, the elimination of redundancy, and the planning to cover existing gaps may offer some possibilities of economy to offset some of the increase. But whatever the target number we select, we must have regard, first to the principles already adumbrated; second, to the danger of opening the doors too wide and not retaining first-class staff owing to competition; and third, to the capacity of society to utilize the students when qualified. On the second point it may be observed here that the question of status and standards among the university staffs is of first-class importance. Quality must come before quantity and there must at least be that much relation between the financial rewards in a university career, whether of teaching or research, and those elsewhere, to ensure that a due proportion of the ablest minds of each succeeding generation are attracted to such careers. Accordingly no policy of university expansion which neglects to bring such matters as staff salaries and grading, superannuation, and the like, more into keeping with conditions in industry will achieve its purpose. Beyond this, if a university is a free and graded association of free men and women united in a corporate organization to study apart and develop truth, no limits can be set to the institutional forms its activities may take or to the spheres of conduct in which it may fruitfully intervene, other than those which in practice mere prudence will dictate to avoid the unwise diffusion of resources.

The third point requires somewhat fuller consideration. Mannheim has directed attention to the dangers which arise when there are more persons on the intellectual labour market than society as it is requires for carrying out its intellectual work. It is, of course, true that one of the reasons for expanding the universities of Great Britain is that at present industry is making insufficient use of scientific knowledge because it does not employ in the right positions a sufficient number of those trained to use such knowledge. It is also true that the demand for such workers has increased and that progressive firms already anticipate a difficulty in finding sufficient recruits of the requisite calibre unless the university schools of research are expanded. None the less, the warning which Mannheim gives of the effect of over-supply on society in the lost social value of the intellectual professions and the belittling by public opinion of cultural and intellectual activity is not one to be disregarded if we hope to plan for a new society and to preserve the essential elements of freedom and culture; and that warning is powerfully enforced by experience in Germany.

What, then, in short should be our basic strategy with regard to the universities and research? First, we must look to them for the supply of the research workers required in all branches of science and for industry, for government institutions and departments, and for fundamental research at the universities themselves. Second, we must look to them ultimately for the supply of leaders in all walks of society competent to apply scientific knowledge to the service of industry or of the nation as a whole. Thirdly, we must look to them to play a vital part in that work of adult education through which alone we can hope for a society in which policies and plans based on scientifically ascertained facts can be assured of reasoned and general support. Finally, these teaching functions must be in balance with the equally vital function of research of extending the bounds of knowledge.

That last task must be considered more fully in connexion with the actual organization of research. It is sufficient to note here that teaching must be in vital touch with research, and that we may have to consider more carefully to what extent the two functions can be combined in the same staff. That there must be the vital contact is not denied, nor the value to the research worker himself of attempting to expound to others the significance of the field in which he is working. What we are concerned with is raising the standard of teaching and with giving to the really great teacher with a genuine talent for exposition and for inspiring others the full scope and encouragement that he deserves. Such teachers are not necessarily great investigators also, and one reason for the inadequate appreciation of science is certainly the failure of scientific workers themselves to accord fitting status and prestige to the great expositor in their ranks. We would do well, as Sir J. J. Thomson urged, to pay far greater regard in our appointments to teaching posts, whether of professors or lectureships, to the powers of the candidates to present a subject in a clear and attractive way.

These relations will demand especial consideration with regard to the social sciences, where university study has important contributions to offer in clarifying the issues involved in many social and economic problems to-day, both in regard to methods and assumptions, and the problem of values and moral issues. Never was it more important that the univer-

sities should be places where thought and disinterested inquiry are pursued on the highest level, and where the best minds of each generation are trained for intellectual achievement. Teaching and research alike in the universities must be pursued in a spirit entirely free from bias, prejudice or preconceived ideas.

The first two tasks, however, must be related quantitatively to some reasonable estimate of the needs of society for university graduates, first in the immediate post-war period, but finally to the long-term needs. That relation should be sufficiently flexible to minimize any over-training likely to hamper transfer or adjustment as the needs of society shift slightly from one field or branch of science. Clearly such flexibility must be had in mind in considering afresh the content of university curricula. Clearly also such quantitative relations involve a much fuller study of the structure of society and of the technique of social adjustment, for which provision also must be made in the organization set up to implement our strategy. Furthermore, limitation of the numbers of students entering the universities presupposes, as the British Association Committee emphasizes in its report, much more care in selection. When the number of places is limited, there can be no longer room except for those possessing the appropriate qualities of ability and character, though originality and creative needs should be our first concern here.

Qualitatively, all these four tasks alike involve loyalty to the conception of the university as a place where teaching and research are linked inseparably, set forth so consistently by Rashdell and by so many of those who have since touched this theme, but by none better than by Haldane: "A place of research, where the new and necessary knowledge is to be developed; a place of training where the exponents of that knowledge—the men who are to seek authority—are to be nurtured, and receive their spiritual baptism. Such a university cannot be dependent in its spirit. It cannot live and thrive under the domination either of the Government or the Church. Freedom and development are the breath of its nostrils, and it can recognize no authority, except that which rests on the right of Truth to command obedience".

Whatever the magnitude or directions which university expansion may take, those ideals must be served, and such service will assuredly demand all the inspiration and vision that the universities' greatest traditions of independent and fearless inquiry and faithful service can supply. In a memorable passage Rashdell described the service the University of Paris rendered in checking in France the dangerous tendencies of the Inquisition in Spain.

"The political position of Paris gave its university a place in the political and ecclesiastical world which no other university has ever occupied . . . a body of educated men, protected by the sanctity of their order against the hand of secular justice, possessing the right of public meeting, of free debate, and of access to the throne. The tendency of a body so situated to become a great organ of public opinion, a channel through which the Court might address itself to the nation, and the voice of the nation reach the Court, was strengthened by the deliberate policy of the House of Valois".

The point which Rashdell here makes that at a particular crisis in the history of Europe the universities performed the function which is discharged at the present time by the Press, the platform or even by the polling-booths is of wider significance than as illustrating that Rashdell was fully aware of the social functions of the universities. It is even more explicitly shown in his reference to the University of Oxford: "It was not as a great semi-ecclesiastical corporation but as a centre of speculative thought and of religious life, that Oxford contributed to the making of English history. It was through her influence upon the religious life of England that the University of Oxford did at one supreme moment open a new page in the history of England and of the civilized world."

No one can ponder such passages without glimpsing something of the possibilities if the universities recognize the opportunities which confront them and face the task of reconstruction and development in a like spirit. There is need for fundamental thinking, for close analysis and wise organization and marshalling of resources, which however much they are augmented are bound to be limited. But creative thought and wise administration alike will be most fruitful as in loyalty to these ideals and traditions of the past the universities seek to discover the new forms and opportunities of service which are opening before them, and to grasp them surely in ever more active and intimate co-operation with the whole community upon which in part their own spiritual and intellectual effectiveness in enriching the national life depends.

## THE APPRECIATION OF SCENERY

**The Beauties of Scenery**
A Geographical Survey. By Dr. Vaughan Cornish. Pp. 128+16 plates. (London: Frederick Muller, Ltd., 1943.) 6*s*. net.

THE scientific study of scenery, which owed so much to Sir Archibald Geikie, Lord Avebury, and later to J. E. Marr, has benefited greatly in recent years from the writings of Dr. Vaughan Cornish. He has not only devoted himself to the problems of the preservation of scenery and to the related question of national parks, but has sought also for a new approach to the appreciation of scenery. He has endeavoured to develop an analytic study of beauty in scenery, and in this new book he has sought to provide a manual on this subject, which he hopes may be useful as a basis "for education in scenic amenity in preparation for the re-planning of town and country".

His approach to the scenery of an area is influenced by his geological and geographical interests. Indeed it is certain that any real understanding of scenery must have a geological basis (especially if geology is taken to include physical geography). It may readily be admitted that many have a warm appreciation of the beauties of scenery without such a geological basis; but it can be claimed that some knowledge

of the geological structure and the moulding of the foundations of a landscape clarifies the vision and enlarges the interest. It is regrettable that so little reference is made to these simple geological factors in school work. What is needed is not so much a formal study of the science with numerous technical terms, but rather an indication of some of the influences of the rocks on life and landscape.

The author of this little book has set himself a considerable task in attempting to cover a very wide field in such a small compass. In his first chapter he has discussed the sky by day and night, clouds, rainbows, the Arctic summer, eclipses, stars, comets and the aurora, all in eighteen pages.

But still more compression has been required in the second chapter, in which Dr. Cornish deals with "Land and Water". The coast-line of southern England illustrates many of his early points, but after little more than two pages we are rushed away to the coasts of the Riviera and to Norway and New Zealand. The scope is so wide that the discussion is tantalizingly brief, and the change of topic is so sudden that there is a suggestion at times that one is reading a series of notes rather than a connected study. Yet from this chapter the reader will gather some indication of the geological factors affecting scenery, and it may be hoped that he will be stimulated to seek more elaborate accounts of the landscapes familiar to him. Some suggestion of suitable books for further reading on these topics would have been useful.

After a chapter on natural vegetation and wild life, in which mammals and birds are taken to be as essential a part of the scenery as man himself (especially the colours of his clothing), there are two chapters on the scenery of civilization. Here Dr. Cornish gives an account of many types of architecture, from Swiss chalets and Cotswold cottages to the buildings of Washington and Rome, from megaliths to skyscrapers.

In his last chapter the author has somewhat extended the meaning of scenery to include "indoor scenery". This naturally affords him an opportunity of writing about the architecture of interiors of houses and churches; but it is rather surprising to find the theme still further enlarged by the inclusion of screens and mural painting, and then of furniture, carpets, convex mirrors, and finally, the engraving of coins.

There is, however, one approach to scenery to which the author makes no reference, but which will surely be of increasing interest in the future, that is, the aspect of the country as seen from the air. While there are some who find air journeys intolerably dull, there is much of interest and of beauty to be seen from the air which is not apparent from the ground: the wide sweep of landscape features, the changes in crossing the broader climatic belts (for example, over Africa), and the amazing colours and patterns of shallow seas when flying along a coast-line, especially when the water is clear. Even aerial photographs, the use of which is certain to increase after the War, show many aspects of scenic design. With the increase of civilian flying there will be an opportunity to provide passengers with data to make journeys more fascinating and to widen their interest in the history of scenery.

It remains to add that Dr. Cornish's volume is illustrated by thirty-two photographs showing many of the features with which he deals.

A. E. TRUEMAN.

## CHEMICAL EXAMINATION OF WATERS

**The Chemical Analysis of Waters, Boiler- and Feed-Waters, Sewage, and Effluents**

By Denis Dickinson. (Blackie's 'Technique' Series.) Pp. xii+140. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1944.) 6*s*. net.

THIS latest addition to Blackie's "Technique" series of handbooks maintains the high standard of earlier volumes. It is a very practical guide to the wide subject of water analysis, and has been written primarily to meet the needs of the industrial chemist.

A chemical analysis of water may be undertaken for a variety of purposes; for example, to test its suitability for drinking, washing, feeding boilers, or discharge to a stream. It will thus be realized that the tests to be applied will depend very largely upon the purpose for which the analysis is made; and the book under review deals with most of the tests which could come into consideration. The details given of the tests are sufficient to enable the industrial chemist to carry them out, but the book would have been enhanced in value if the author had indicated the interpretation to be placed upon the results of the analysis.

Perhaps in no branch of chemical analysis are there so many tests as there are in water analysis which depend for their result upon a strict observance of the various conditions under which the test is carried out. This is sufficiently indicated in the several chapters of the book dealing with oxygen tests for organic matter, the biological oxygen demand, and determination of albuminoid nitrogen. These facts cry out for a standardization in methods of carrying out tests, and it is most important that greater uniformity should prevail, so that the results obtained by one analyst may be comparable with those obtained by another. The author does touch upon this aspect of standardization, both in regard to the methods of carrying out the tests and the method of expressing results, but he does not take sides for or against.

The fourteen chapters of the book are very well written, and although it might be considered invidious to select any chapters for special mention, those dealing with hardness and boiler-feed and boiler-waters are specially worthy of praise. It may be that they indicate some special interest of the author.

It is important when reading a book of this kind to bear in mind that chemical analysis alone only affords an incomplete picture of a water, and that in considering, for example, its suitability for drinking purposes, the chemical analysis should be supplemented by a bacteriological examination. Such an examination is perhaps not always so important in connexion with trade effluents.

The book presents a very wide review of the subject with which it deals, and the reference to fluorine as being responsible for the condition known as dental fluorosis is specially to be welcomed. The latest information on this subject has been included. Reference might have been made to the radium content or radioactivity of waters, a subject which is deserving of more attention than it has received in the past.

In an appendix the author includes typical analyses of various kinds of water, including drinking water, sewage and sewage effluents and a variety of trade

effluents. Typical analyses of waters used for locomotive boiler-feed are also included.

In conclusion, the book is a useful compilation which should prove of value not only to the industrial chemist but also to all those who have to examine waters as to their suitability for the many purposes for which they find a use. As the author says, he has only attempted to include a fraction of the known methods of analysis, and for other methods it would be necessary to refer to the larger text-books; but as already stated, he has provided an excellent guide to the wide subject of chemical analysis of waters.

H. T. CALVERT.

# NUTRITION AND HEALTH

## Nutrition and National Health

Being the Cantor Lectures delivered before the Royal Society of Arts, 1936. By Major-General Sir Robert McCarrison. Pp. 75+3 plates. (London: Faber and Faber, Ltd., 1944.) 6*s*. net.

THIS attractively written book is a re-publication of the three Cantor Lectures delivered to the Royal Society of Arts in 1936. The author was formerly director of research in nutrition in India.

The first lecture is devoted to the physiology of nutrition; the second to the relation of oxygen, water, proteins, mineral salts and vitamins to health and illness; the third to the effects of nutrition on national health. The whole constitutes a useful introduction to the study of a subject much in the public mind at present, illustrated throughout by references to the author's work in India and to results obtained in Great Britain.

If criticism is to be made, it might suggest that the opportunity of reprinting could have been taken to include some account of the creation and work of the Nutrition Society, that more recent researches might have been included and that more space might have been given to nutrition of those animals on which we depend for our food supplies and to the effects of the national food policy during this War. The education of the public, the medical student, the medical practitioner, the school teacher and others for which Sir Robert appeals has surely been going on vigorously in recent years, and the public is already very conscious of food values. It has learned, too, the pleasure and advantage of growing its own greenstuffs and of producing its own eggs, thanks to the national policy of aiding both these enterprises. It may still be true that greenstuffs have already lost much of their food value before they reach the poor, but this can only be true of large cities and only of parts of these; for everywhere within and outside them allotments have been growing vast quantities of vegetables for some years, and it is a little late in the day to advocate, as Sir Robert does, the extension of these and of facilities for keeping poultry. There are parts of the country, indeed, in which people cannot eat all the greenstuffs that they grow.

The book is a beautiful example of what can be done within the limits of the authorized war-time standards of economy. Some readers will wonder why, if books like this can be produced within such limits, more of them do not appear. For the same reason some may even wonder whether any other standards will be really needed after the War.

G. LAPAGE.

# PHILOSOPHY OF ORGANISM

## A Contribution to the Theory of the Living Organism

By Prof. W. E. Agar. Pp. 207. (Melbourne: Melbourne University Press; London: Oxford University Press, 1943.) 12*s*. 6*d*.

THE keynote of Prof. Agar's book, in which he has drawn freely upon the materials both of philosophy and biology, is frankness, directness and lucidity. At least some preliminary contact with the biological philosophy of Whitehead is demanded of the reader. The main thesis is that all living organisms are subjects, that all, possibly including even the simplest, are organizations of subjects, and that the characteristic activity of a subject is the act of perception. In this perception he sees the establishment by the subject of its causal relation with the external world. Even in inanimate objects, process is conceived as one of experience or feeling. In developing this thesis, in which Whitehead's philosophy of organism is freely invoked, many aspects of the organism, especially those of which we have knowledge from experimental investigation, are discussed with refreshing lucidity.

In treating the component parts of living organisms, even at the level of cells or cell aggregates, as feeling, perceiving subjects, the author realizes that he is introducing an interpretation which is likely to be opposed or denied by many biologists. Thus, for example, he writes: "As perception always carries with it the anticipation of further relevant experience, and the meaning of the present experience includes action, or potential action, appropriate to the anticipation, the notion of final causation is involved . . . the anticipatory aspect of causation compels us to recognize the reality of final causation in all perceiving organisms". Thus, in this connexion the teleological nature of causation is recognized. The author is well aware that in adopting this point of view he is treading dangerous ground—that in which science and philosophy stand in danger of becoming confused—but he is prepared to maintain his position and to justify his views. The thesis which, in some respects, is the antithesis of a mechanistic theory, thus rejects the view that "biology is only a science so long as it is only biochemistry and biophysics".

Consideration is given to such topics as purposive action and its interpretation, the unity of the organism considered in the light of experimental studies, biological fields, *Gestalt* psychology, animal behaviour in terms of perception, and aspects of embryonic development and its interpretation as behaviour. In a final chapter the conclusions reached are considered in relation to the Darwinian and Lamarckian views of the process of evolution, a verdict in favour of the former being given. If his thesis is correct, says Prof. Agar, biologists must accept perception as one of their ultimate data; but he admits that even in imagination it is not easy to trace "the detailed course of the evolution of the higher out of the lower types of perception".

No adequate short review of this book is possible, for the book is itself commendably short, and while full of meat, yet does not give the impression of being crowded. If biologists admit that they should give heed to the trend of thought in Whitehead's philosophy of organism, as sooner or later it seems they must, then they would do well to read this book.

# CURRENT PROBLEMS OF VISUAL RESEARCH

By DR. W. S. STILES
National Physical Laboratory

## Variations in the Visual Threshold

THE problems of visual research discussed in this lecture mainly concern the sensitivity of the retina. A very general test of retinal sensitivity is the determination of the threshold increment, or, briefly, the threshold. The eye views a given distribution of brightness—which may be varying with time in a prescribed way—and, at a given moment, a small additional light stimulus is applied at a particular point in the visual field. By repeated trials with different intensities of the additional stimulus, the critical intensity can be determined at which the observer sees the stimulus on fifty per cent of occasions. This threshold increment, or better, its reciprocal, provides a measure of the sensitivity of a given part of the retina at a given time. It can be determined under a wide range of conditions, and by varying the angular size, exposure time and colour of the test stimulus the response can be made to depend in different degrees on different mechanisms in the retina.

In a typical determination of the threshold increment by the method now commonly adopted, an S-shaped curve is obtained showing how the chance of seeing the test stimulus varies with its intensity. Frequently, there is a considerable range of stimulus intensities, of the order of 3 to 1, within which it is a matter of chance whether the stimulus will be seen. This range of indefiniteness is commonly attributed to uncontrollable variations in the sensitivity of the retinal or post-retinal processes in the observer. Some years ago, however, it was suggested in several quarters[1,2,3] that for an eye in its most sensitive state the threshold is so small that *quantum fluctuations in the stimulus* might be responsible for a part of the observed scatter.

The threshold, expressed as the number of quanta of radiation entering the eye from the test stimulus, has its smallest value when the eye is fully dark-adapted and when the test stimulus is a very brief flash (0·01 sec. or less) from a point source (10 min. diameter or less) of green light ($\lambda = 510\ m\mu$) which is viewed by slightly averted vision, so that the image is formed on the parafoveal retina. Under these conditions the threshold has a value of about 50 quanta. Because of the corpuscular nature of radiation, any physical apparatus designed to flash a fixed number, say, $N$, quanta into the eye can do so only on the average, the actual number varying about $N$ with a standard deviation of $\sqrt{N}$. Thus, even if the subject invariably responded when 50 or more quanta entered the eye, a flash of nominally 40 quanta would sometimes contain 51 quanta and would be seen, whereas one of nominally 60 quanta would sometimes contain only 49 quanta and would be missed.

But quantum fluctuations on 50 quanta are too small to explain the whole of the scatter evidenced in the experimental S-shaped curves, and there seemed no satisfactory way of separating quantum from biological fluctuations. Recently a big step forward was made by Hecht, Shlaer and Pirenne[4], who advanced strong reasons for thinking that quantum fluctuations are the main factor. They made new determinations of the threshold under the optimum conditions indicated above and obtained values ranging from 54 to 148 quanta for seven observers. They estimate that, of the light incident on the cornea, only about half reaches the retina, the other half being lost by absorption, reflexion or scattering in the optic media of the eye. The crux of their argument is, now, that of the light reaching the retina, at most 20 per cent is actually absorbed by the visual purple, the light-sensitive substance in the retinal rods, which are certainly the end-organs by which the stimulus is seen under the conditions of the threshold measurements. They arrived at the figure of 20 per cent from estimates of the total quantity of visual purple in the retina and from a comparison of the spectral absorption curve of visual purple with the scotopic visibility curve. They conclude that the threshold increment of 54–148 quanta measured outside the eye corresponds to an absorption of at most 5–14 quanta in the retinal rods, and these latter numbers are the ones on which the quantum fluctuations must be assessed. Assuming that the absorption of $n$ quanta (or more) will always produce a visual response, the S-shaped curve can be calculated from the Poisson probability formula for any value of $n$. Hecht, Shlaer and Pirenne found that their experimental S-shaped curves fitted the calculated curves for values of $n$ ranging from 5 to 7 (see Fig. 1). The agreement with the upper limit of 5–14 quanta, derived from the absolute value of the threshold, is remarkably close, and these workers draw the conclusion that quantum fluctuations of the stimulus are the main cause of the indefiniteness of the absolute threshold of vision.

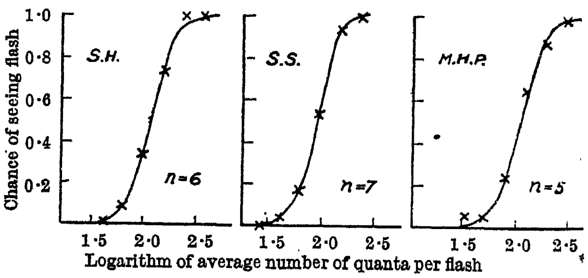

Fig. 1. RELATION BETWEEN THE CHANCE OF SEEING THE STIMULUS AND THE NOMINAL INTENSITY OF THE STIMULUS. THE PLOTTED POINTS ARE THE EXPERIMENTAL VALUES: THE CURVES ARE CALCULATED FROM THE POISSON DISTRIBUTION ASSUMING THE EFFECTIVE NUMBER OF QUANTA IN THE VISUAL ACT TO BE 6, 7 AND 5 FOR THE RESPECTIVE OBSERVERS. (FROM HECHT, SHLAER AND PIRENNE[4].)

The conclusion applies in the first instance to monochromatic green light (510 $m\mu$), the radiation to which the dark-adapted eye is most sensitive, but it is probably equally valid for other wave-lengths. For these other colours, although the number of quanta in the threshold flash outside the eye may be many thousands, the number actually absorbed in the rods and thereby participating in the visual act is reduced to the same value as for green light by the smaller absorption of the visual purple. It is also possible that when the retina is adapted to brightness levels above zero, the scatter of measurements of the threshold increment is still mainly determined by quantum fluctuations.

The S-shaped curve has a bearing on another interesting visual question—the problem of summa-

* Abridged from a lecture before the Physical Society delivered on May 24.

tion. If two or more similar patches of light are sufficiently close together in a dark field of view, they are visible at a lower brightness than a single patch. If the patches are small, say, 0·1° in diameter, and contained in an area of about 1° diameter, the threshold brightness for ten patches is about one tenth that for one. This is an example of physiological summation. The patches assist each other by some retinal interaction which has a very limited radius of action. If the patches are widely separated, however, a kind of summation is to be expected merely as a result of the scatter of the threshold evidenced in the S-shaped curve. If for a given patch brightness the chance of seeing a single patch is $p$, the chance $P$ of detecting a group of $n$ patches is the chance of not missing every patch, or $1-(1-p)^n$. This is provided the chance of seeing a given patch is independent of the presence or absence of the other patches. From an experimental S-shaped curve for $p$, the corresponding curve for $P$ can be calculated from the formula just given, for any value of $n$, and the relative thresholds for the single patch and the group can be determined. Meatham and Lambert[5] discuss this point in their work on the visibilities of groups of light patches seen against a starlight background, and from their S-shaped curve for $p$ they calculate that four patches would reduce the threshold brightness by a factor of 0·85, and that for a very large number of patches the reduction factor would be about 0·6.

Summation of this kind may be called probability summation, to distinguish it from physiological summation, which occurs in the retina or other more peripheral parts of the response process. Its operation does not depend on the cause of the scatter evidenced in the S-shaped curve, which may be either quantum or biological fluctuations or some resultant of the two.

Pirenne[6] has independently applied a similar idea to binocular summation in the perception of a point flash by the dark-adapted eye.

## Visibility Curves under Different Conditions

Recently visibility curves for both fovea and parafovea have been determined by the brightness matching method, using a sufficiently small matching field for the retinal properties within it to be fairly constant. In this work of Walters and Wright[7], measurements were made from near threshold up to quite high brightnesses of the matching field, and the gradual change in the form of the parafoveal visibility curve from a typical rod curve with maximum at about 510 mμ to a typical cone curve with maximum at about 560 mμ was established. At the lowest brightnesses used, the form of the visibility curve in the red end was still changing, indicating that the cones were still having some effect.

It is of interest to try to interpret the changes in the parafoveal visibility curve, using the picture of the rod-cone transition which is presented by measurements of the threshold. The change in the parafoveal threshold as the brightness level is raised follows a curve such as that shown in Fig. 2, which refers to a green adapting brightness and a yellow test stimulus. There is no reasonable doubt about the meaning of this curve. The lower part represents the threshold of the rod mechanism, the upper part the threshold of the cone mechanism.

Experiment shows that if the wave-length of the test stimulus is changed, say from 580 to 500 mμ,

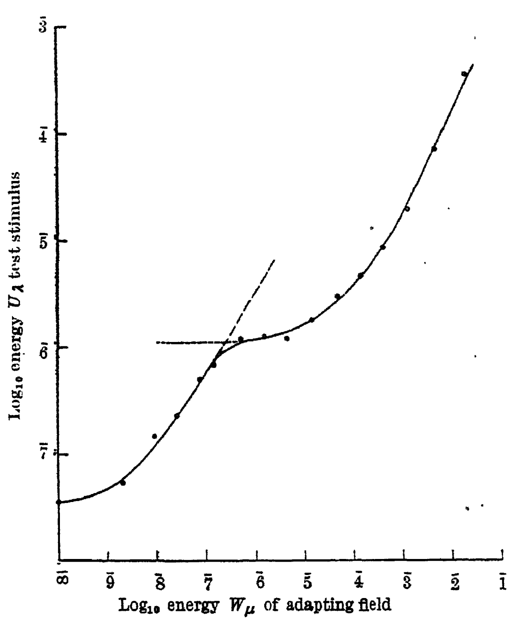

Fig. 2. 5° PARAFOVEAL THRESHOLD FOR A TEST STIMULUS OF WAVE-LENGTH 580 mμ AND AN ADAPTING FIELD OF WAVE-LENGTH 500 mμ. (FROM STILES[8].)

the rod component curve is moved bodily down to lower energy thresholds because the rods are more sensitive to light of wave-length 500 mμ. The cones, however, are less sensitive to this wave-length and the cone curve moves up. Change in the wave-length of the adapting field produces similar bodily shifts of the component curves, but parallel to the horizontal axis.

By a reasonable generalization of these experimental results[8] the condition that the two halves of a photometric field, viewed parafoveally, shall be on the threshold of discrimination is obtained in the form:

$$1 = \left[\frac{\delta\sigma}{F_s(\sigma)}\right]^2 + \left[\frac{\delta\pi}{F_p(\pi)}\right]^2 \quad . \; . \; . \; (1)$$

where $\sigma$ and $\sigma + \delta\sigma$ are the scotopic values, and $\pi$ and $\pi + \delta\pi$ are the photopic values of the lights in the two halves of the field. The scotopic and photopic values of a light of energy distribution $W_\lambda d\lambda$ are defined as $\sigma = \int W_\lambda s_\lambda d\lambda$ and $\pi = \int W_\lambda p_\lambda d\lambda$, where $s_\lambda$ and $p_\lambda$ are respectively the spectral sensitivity curves of the rod and cone mechanisms. The fixed functions $F_s(x)$ and $F_p(x)$ are determined by the shapes of the rod and cone component curves of Fig. 2. By applying a method due originally to Helmholtz[9] the threshold condition (1) can be used to derive a step-by-step visibility curve for any intensity level of the matching field. Curves calculated in this way are compared with a selection of Walters and Wright's experimental curves in Fig. 3.

As the brightness level is raised, both the observed and theoretical curves[10] show initially a rise in the red and later a shift of the maximum towards the red, and the intensities at which these changes occur are in fair agreement. It should be observed, however, that the step-by-step method was not used by Walters and Wright; they used a fixed red comparison field. At high brightnesses, the step-by-step and the fixed comparison field visibility curves are substantially the same, but this may not be so in the transitional

D, mean photopic visibility curve

region. Nevertheless, this tentative application of the Helmholtz method suggests that it may prove of use in interpreting on a common basis the threshold and brightness matching results.

The Helmholtz method of deriving a step-by-step visibility curve from threshold measurements can also be applied to foveal vision. Here, instead of two mechanisms, rods and cones, there are three mechanisms to consider, the three kinds of cone. The threshold condition takes the form:

$$1 = \left[\frac{\delta x}{F_r(x)}\right]^2 + \left[\frac{\delta y}{F_g(y)}\right]^2 + \left[\frac{\delta z}{F_b(z)}\right]^2, \quad . \; . \; . \; (2)$$

where $x = \int W_\lambda r_\lambda d\lambda$, $y = \int W_\lambda g_\lambda d\lambda$, $z = \int W_\lambda b_\lambda d\lambda$ and $r_\lambda$, $g_\lambda$, $b_\lambda$ are the spectral sensitivity curves of the three cone mechanisms. These curves and the fixed functions $F_r(x)$, $F_g(x)$, $F_b(x)$ have all been determined to a first approximation from measurements of foveal thresholds. The derived visibility curves, (a) for very high field brightness, (b) for a brightness at the level normally used in photometry, are shown as the plotted points in Fig. 4. The agreement with the C.I.E. visibility curve is promising.

The colour perceptions in the parafoveal retina are not radically different from those in the fovea, and it must be assumed that there, too, three cone mechanisms are operative. The discussion of the parafoveal visibility curve should therefore have been based on a four-dimensional threshold condition:

$$1 = \left[\frac{\delta\sigma}{F_s(\sigma)}\right]^2 + \left[\frac{\delta x}{F_r(x)}\right]^2 + \left[\frac{\delta y}{F_y(y)}\right]^2 + \left[\frac{\delta z}{F_z(z)}\right]^2 \; . \; . \; (3)$$

It is not difficult to see, however, that the resulting visibility curves would not be materially different from those obtained on the simpler view. But the form of the result raises a difficult question in our ideas of the visual mechanism. At the fovea, the two halves of the field will match in all respects if $\delta x$, $\delta y$ and $\delta z$ are small, that is, if three relations of the form $\int r_\lambda W_\lambda d\lambda = \int r_\lambda W_\lambda' d\lambda$ approx. are satisfied. In the parafovea it appears that four such relations would have to be satisfied, which apparently contradicts the main tenet of the trichromatic theory.

Psychologists, in particular Katz[11], have emphasized that hue, saturation and brightness are not the only modes of appearance of colours. It is conceivable that another modality, for example, a 'filminess-solidity' differentiation, might be manifest in parafoveal vision, and that to equate parafoveal fields in this respect, as well as in hue, saturation and brightness, a fourth variable would be required. However this may be, the immediate requirement for an attack on this interesting visual problem is a thorough investigation of colour-matching in the parafovea.

## The Retina in a State of Change

Wright[12] has shown that information about the relative rates of recovery of the different cone mechanisms can be obtained by the method of binocular colour matching. The test light seen by the recovering eye is colour-matched by a mixture of three spectral primaries forming the comparison light seen by the control eye. As recovery proceeds, the varying amounts of the primaries required determine three recovery curves. One of the first problems attacked by Wright was the determination of the visibility curves of the three cone mechanisms, or the fundamental response curves. The underlying assumption was the so-called law of coefficients. This says that if $x$, $y$, $z$ are the quantities of the fundamental primaries (that is, hypothetical primaries each of which stimulates only one of the cone mechanisms) which match the test light before the application of the adapting light, then at a given time $t$ after removing the adapting light the quantities required will be $ax$, $by$, $cz$, where the coefficients $a$, $b$, $c$ are independent of the intensity and colour of the test light. They will, of course, depend on the characteristics of the adapting light and the time $t$. By experimenting with various test lights and adapting lights, Wright was able to derive a set of fundamental response curves which were consistent with the results and with the coefficient law. These seemed satisfactory except for the fact that the green response curve dropped to negative values in the blue end of the spectrum. Although negative values are quite acceptable in colorimetry, they cannot easily be interpreted as a property of a cone mechanism. Recently Walters[13] has shown that the coefficient law is not true in general, and has suggested that it becomes true only in the limiting case of a test stimulus of very low intensity. On this view, he has made a re-determination of the red and green response curves.

The coefficient law may fail because the test light itself is sufficiently bright to modify the recovery process, and this modification may occur to different extents for the three mechanisms. This would not necessarily entail any interaction between the three mechanisms. However, there is evidence of true interaction between the mechanisms. A specially noteworthy effect is the phenomenon of the positive blue[13,14]. If the retina is adapted with a strong red light and a red test light is applied, then within the first few seconds of recovery the test stimulus appears desaturated or possibly purplish, and positive blue has to be introduced into the comparison patch. It might be expected that the red adapting light would

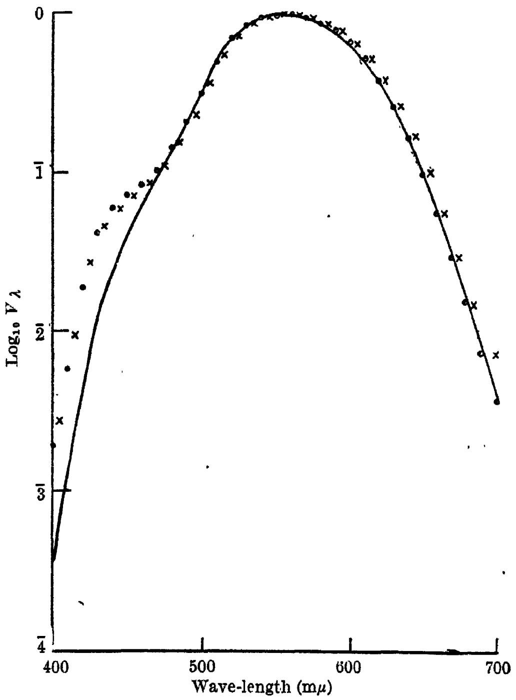

Fig. 4. FOVEAL VISIBILITY CURVE.
⊙, derived by threshold method: very high brightness;
×, derived by threshold method: photometric brightness level (80 photons);
Continuous curve: C.I.E. visibility curve.

fatigue the blue mechanism less than the red or green, but then the red test stimulus would also stimulate the blue mechanism less. The evidence now accumulated seems to rule out any explanation of the positive blue on the basis of three independent mechanisms with constant spectral response curves. It should be noted that the effect cannot be attributed to a blue after-image superposed on, but otherwise independent of, the test light, for it can occur under conditions where no blue after-image is visible in the absence of the test light.

Another type of interaction occurs if the rate of recovery of, say, the green mechanism depends on the instantaneous conditions or on the rates of recovery of the other two mechanisms. Such interaction might not of itself entail a breakdown in the coefficient law. That interaction of the kind in question does occur has been shown by Wright[14], who found that the red and green recovery curves followed different courses depending on whether, in the initial adaptation, the blue mechanism was, or was not, highly stimulated. It is not difficult to conceive how interaction of this type could be brought about if the recovery of the three mechanisms depended on some common and limited reservoir of photochemical material or on some common recuperative substance, such as oxygen carried by the blood.

On the whole, it seems that the notion of three independent cone mechanisms with fixed response curves works fairly well provided the retina has become adapted to the radiation falling on it. It is in the process of changing from one state of adaptation to another that the effects of interaction are chiefly exhibited.

## Fundamental Response Curves

König believed that the principal colour blinds—protanopes, deuteranopes, tritanopes—differed from the normal simply by the lack of one of the three response mechanisms, and his proposed fundamental response curves—*Grundempfindungen*—were chosen largely to fit in with this idea. New measurements by Pitt[15] of the colour-mixture curves, the visibility curve and the hue discrimination of protanopes and deuteranopes, and a reconsideration by him of König's observations on five tritanopes, lead him to the following conclusions. Protanopes lack the red mechanism, tritanopes the blue mechanism, while deuteranopes have in place, of the red and green mechanisms a single mechanism the response curve of which is a weighted mean of the normal red and green curves. His fundamental response curves based on this view and on some other evidence are of the same general type as König's as regards position of the maxima and shape. They are also in tolerably good agreement, in these two respects, with the spectral sensitivity curves of the three cone mechanisms derived from measurements of foveal thresholds. Walters' red and green response curves obtained from binocular matching are consistent with Pitt's curves. It seems that there is an accumulation of evidence obtained in different ways in favour of a set of curves of the König type.

Of recent years a great many measurements have been made, both in Great Britain by Wright[16,17] and his co-workers and in the United States by MacAdam[18], on the hue limen and the more general colour limen throughout the colour triangle. The results have been expressed in terms of the C.I.E. trichromatic system and the so-called uniform chromaticity system. Presumably, if expressed in terms of the fundamental primaries, they would assume a particularly significant form. This does not mean that when so expressed they would exhibit any very obvious or simple property. In particular, they will not show that, in the triangle or in the rectangular system, just distinguishable colours are always separated by a fixed distance. It now seems certain that no linear transformation of the C.I.E. co-ordinates would present the limen measurements in this simple form. The analysis of the data is complicated by the existence of considerable differences between the results of different observers. By the use of *non-linear* transformations of the C.I.E. co-ordinates, Moon and Spencer[19] have succeeded in expressing the complete liminal data of one observer in the much desired form in which a fixed distance in the diagram separates all pairs of just distinguishable colours. The physical implications of this result are not yet clear.

# JOHN TORREY: AMERICAN BOTANIST

By DR. NICHOLAS POLUNIN
New College, Oxford

TO those familiar with the vast and productive western and middle-western regions of the United States, the realization may come as something of a shock that these spacious lands were not only little developed but also very little known a century ago. A recent book* embraces that very important phase of American history—the detailed exploration and development of the West. In it we learn much of the coming and going of expeditions, of the trials of explorers and administrators, and of the discovery of all manner of new features. The West was still a country where exploration in the full geographical sense could be carried out—in contrast to the world to-day which, to be honest, we must admit contains few if any major areas remaining to be discovered or even primarily surveyed—and it was still very much a land of wild Indians and all manner of dangers both known and unforeseen. Much the same was true, in lesser degree, of the Rocky Mountains and many tracts lying nearer to the eastern and southern fringes of civilization.

But the very period of these explorations (well on in the nineteenth century) was one of great scientific awakening and development; and so, fortunately, they saw a telescoping of geographical exposition with the scientific investigation which is the real and none the less fascinating work of the explorer of to-day.

Accordingly to the subject of this biography, the expeditions brought in plant collections in considerable number and variety, which led to his being the first to describe the flora of many areas that had previously remained unknown botanically. At first the recognition of the calls of botany needed activating by the instruction and dispatch of collectors; but in time it seemed to proceed almost automatically. Indeed, the reader might be excused if, in a fit of enthusiasm, he were to conclude that this account of the botanical investigation which proceeded in the United States in the days of John Torrey gave a very fair picture also of the history of American exploration in those momentous times.

Torrey the botanist was born in 1796 in New York, of a New England father of British ancestry, and died early in 1873 in his seventy-seventh year. Though a physician by training and to a considerable extent a chemist by profession, he was practically always a botanist by choice. Botany it was that brought him fame, and, through him, made great the name. His long and active life encompassed those of many famous botanists, whom he helped and encouraged in his own country and corresponded with in other parts of the world—so that the story of his work and times is punctuated with their names and contains long extracts from their correspondence.

We learn much of Amos Eaton, "the first great teacher of natural history in America"; of the scholarly mycologist Schweinitz (a prominent clergyman like the pioneering G. H. E. Muhlenberg, "the father of American botany"); of Nuttall, whom Sir William Hooker termed "a queer fellow" though admitting that "he certainly does contrive to get access to most interesting plants"; of the Hookers themselves, both father and son; of David Douglas and Thomas Drummond; of Major Emory and Colonel Frémont, who frequently botanized instead of fighting; of William Darlington and Chester Dewey the caricologist; of D. C. Eaton, of Yale; of the admirable Engelmann, who for a while practised medicine, but then found the lure of botanical researches irresistible; of Tuckerman the lichenologist and Sullivant the bryologist; of the Bigelows and various LeContes; of John Lindley, of whose "Natural System" Torrey published an American edition in 1831; of C. C. Parry, who brought such distinction to western botany, though he was "one of the quietest men in the world—he *pokes* about and turns over any collection of plants that may be lying about" (according to Torrey, who appeared to agree that this was a good beginning for a botanist); of M. C. Leavenworth and Charles Wilkins Short; of Frederick Pursh, whom Torrey disliked as a man and (as is unfortunately common especially in a youthful civilization) accordingly underestimated as a botanist; of Edwin James, of Long's famous expedition in the Rocky Mountains; of Sir John Richardson and the peculiar Rafinesque; and, most notable of all, of the great Asa Gray, whose chief teacher and 'spiritual father' Torrey clearly was. We also learn much of the American learned societies of that day and this—including the Smithsonian Institution, the American Philosophical Society, the National Academy of Sciences at Washington, D.C., and the Lyceum of Natural History of New York with its successor the New York Academy of Sciences.

The author of Torrey's biography has obviously been at great pains to rout out all manner of data and evidence, both published and unpublished. Nevertheless the resulting publication is not without blemishes—as, for example, a fair quota of misprints and ambiguities, the rather loose literary style and apparent lack of expert editing, and the inclusion of such a welter of fact and seemingly minor detail that the result is at times confusing. Moreover, where so much space is given to the description of expeditions and the routes they took, it is surprising not to find more maps. The characters are also very numerous, coming and going so that the central one is apt to be swamped, and no very clear picture of John Torrey, the man, emerges. However, we are given here and there tantalizing glimpses of the real and rather lovable human being—as, for example, in extracts from his personal letters and in the anecdote about the child John who "considered it a great hardship to be sent after dark into the country . . ." although by day he loved the wild tracts beyond the small heart of contemporary New York.

In short, the book is not easy reading; but the theme is intensely interesting. For Torrey lived in one of the most vigorous phases of American history, a history which is seen in this biography from a new or at least unhackneyed angle—that of a pioneer in taxonomic and phytogeographical research whose experiences should prove valuable to students, botanical or otherwise, of the period or of that noble and fundamental science. For fundamental it is, in that taxonomy (most profitably with the background of its geographical offshoot) deals with the delimitation and identification, and where necessary the description and classification, of biological entities of

* John Torrey: a Story of North American Botany. By Andrew Denny Rodgers, III. Pp. x+352. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1942.) 3.75 dollars or 25s. net.

innumerable sorts and sizes, and little enough botanical or zoological or other connected scientific work of a lasting nature can be accomplished without proper knowledge of what the entities concerned are.

Torrey's botanical publications began in his early twenties and extended, as those of so many devoted botanists have done, over more than half a century and until past the time of his death. In size and importance his papers and books grew through the first volume of his "Flora of the Northern and Middle Sections of the United States" (1824), then his monumental two-volume "Flora of the State of New York" (1843) and his joint work with Asa Gray on the "Flora of North America" (1838–43), which was the most searching and authoritative treatment of North American plants up to that time. Most of the expedition reports followed, though often in intervals between work at other subjects.

Torrey lived in the days when, at least in the New World, a man of science could easily be a 'professor' (the title often meaning less in America than in Europe) of different subjects at different times, or even of different subjects at the same time; and in fact Torrey was, as a young man, professor of chemistry and mineralogy at West Point, and later for many years professor of chemistry at Princeton and at the same time professor of botany and chemistry at the College of Physicians and Surgeons of New York (part of what is now Columbia University), where he had graduated. As a chemist he appears to have discovered pectin, which he called "sclerotin", while his chemical knowledge and ability received high recognition later in life when he was made United States assayer; but always he was in touch with, and usually he had a hand in, anything of importance, botanically speaking, which was going on in that rapidly developing country.

As a man Torrey was predominantly straightforward and hard-working, clearly owing his deserved and lasting fame to the consistent expression of these qualities through a life-long devotion to his favourite subject. He appears during his life-time to have been highly respected and widely loved. In the words of one of the most eminent of his successors in the modern practice of taxonomy, Prof. M. L. Fernald, of Harvard, "Torrey was exact, scholarly, a kindly and devoutly religious man, and in the goodness of his heart ready to help everyone". I have heard Prof. Fernald refer to Torrey's descriptions of plants as "wonderfully vivid and accurate, models to this day" —high praise indeed from the director of the Gray Herbarium, whose great founder was Torrey's pupil, assistant and then associate over a total span of more than forty years.

Gray himself styled Torrey "an investigator . . . characterized by a scrupulous accuracy, a remarkable fertility of mind, especially as shown in devising ways and means of research, and perhaps by some excess of caution", who had a "thorough love of truth for its own sake" and "took a prominent part down almost to the last days of his life" in putting into order and describing the materials coming in almost interminably from the exploring expeditions of the time. All this appeared to result from the circumstance that, as a boy, Torrey had been taught by Amos Eaton "the structure of flowers and the rudiments of botany" when Eaton was serving a term in the New York State prison, of which Torrey's father, Alderman William Torrey, was then fiscal agent. Eaton seems to have taught in such a way as to 'awaken a taste and kindle a zeal that could be extinguished only with the pupil's life'. How much greater in our scientifically enlightened days are the data and chances of the educator, and how vitally important his task!

The effect which Torrey has had on botanical knowledge and institutions in America can scarcely be over-emphasized. His name is commemorated in a 'unique' genus of the Coniferæ, in numerous species of vascular plants, in a noble peak in the Rocky Mountains, and in the splendid Torrey Botanical Club; his herbarium exertions "representing a deal of back-ache" went far towards starting two of the greatest herbaria of the world, namely, the United States National Herbarium and the Herbarium of the New York Botanical Garden. Essentially an *American* botanist, finding more than enough to do within the confines of his own sub-continent, Torrey was content to describe rather than to classify, to investigate rather than to theorize—wisely leaving to others, whom he knew would come, the generalization for which he realized the time to be unripe.

Although essentially a practical man, Torrey was to a considerable extent a 'cabinet' botanist, though living in the days when such were needed. He did not experience the thrills and adventures of the actual explorers whose results he worked out so tirelessly and meticulously. His were rather the thrills and adventures of research—the excitement of the microscope and of testing the validity of speculations—the joys which strict compliance with the requisites of minute analysis may bring: for his was the imagination which can see a verdant treasure in a dried specimen. He had the all-important taxonomist's flair; and had he lived in these days of cytogenetics and physecology there can be little doubt that he would have backed or underlain this flair with far more field observation. As things were, however, he was hard put to it, in the midst of other and often more lucrative duties, to arrange and assort, then diagnose, name and describe, the new things which came to him almost daily. There is something of greatness in the man who can sit and wait and have all that he wants come to him; and in the aggregate Torrey must have named and described some thousands of new species and varieties of plants.

In most modern countries, as in the United States of America, botany is a great subject with a vast following both professional and lay—especially among the enlightened who realize that it is by plants that man is largely surrounded, and on them that he lives—consequently its study is imbued with sentiment and historical flavour. In deference to this we may appropriately conclude the present account by quoting Asa Gray, who thus closed his obituary notice of Torrey's life: "Thirty or forty years ago, a new and remarkable evergreen tree was discovered in our own Southern States, which it was at once determined should bear Dr. Torrey's name. More recently a congener was found in the noble forests of California. Another species had already been recognized in Japan, and lately a fourth in the mountains of Northern China. All four of them have been introduced and are greatly prized as ornamental trees in Europe. So that, all round the world, *Torreya taxifolia*, *Torreya Californica*, *Torreya nucifera*, and *Torreya grandis*—as well as his own important contributions to botany, of which they are a memorial—should keep our associate's memory as green as their own perpetual verdure".

# OBITUARIES

## Brevet-Colonel F. Percival Mackie, C.S.I., O.B.E.

BREVET-COLONEL MACKIE, who had a distinguished career in the Indian Medical Service, died at Oransay, Birnam, on July 15. At the time of his death he was chief medical officer to the British Overseas Airways Corporation in London. He leaves a widow and three sons.

Born on February 19, 1875, son of the Rev. John Mackie, rector of Fylton, Glos, he was educated at Dean Close School, Cheltenham, the University of Bristol, and St. Bartholomew's Hospital. After graduating in medicine and surgery at the University of London he entered the Indian Medical Service in 1902, taking first place in the competitive examination of that year and winning the Gold Medal in medicine and the scholarship in surgery. Later in his career he added the F.R.C.P. and the F.R.C.S. as well as the D.P.H. to his professional qualifications.

In India, after a short period of military duty which included a tour as medical officer to the Younghusband Mission to Tibet, he elected for the civil side of the Service with the object of devoting himself to bacteriology and medical research, for which, at that time, organized arrangements in India were in an early stage of development. It was the time when the terrible drama that was being played by malaria, cholera and plague had confirmed the Government of India in its intention to establish an effective organization of bacteriological workers and laboratories, and when several outstanding discoveries in tropical medicine had inspired and stimulated qualified members of the Service to engage in one or other of the young sciences (particularly bacteriology, protozoology and medical entomology) which offered a prospect of finding effective means of control and prevention. Plague, which had appeared in Bombay in 1896, was still spreading eastwards and northwards throughout the country, and Mackie's first appointment in the newly created Bacteriological Department of the Government of India (which was afterwards known as the Medical Research Department) was to the Plague Research Laboratory, Parel, Bombay. This was in 1905, the year in which the British Plague Commission under Dr. C. F. Martin, director of the Lister Institute, arrived in India and selected the Parel laboratory as its headquarters. In this appointment Mackie shared in the brilliant work of the Commission which, as is well known, settled the question of rat-flea transmission and gave to India, and the world in general, fundamental knowledge of the epidemiology of plague to which little was added in later years.

From September 1908 until November 1909 Mackie was on deputation to Uganda as a member of the Royal Society's third Sleeping Sickness Commission under Sir David Bruce. On his return to India he again took up his post at Bombay.

In 1911 the Government of India deputed him for special research again, this time to study kala azar in Assam. The causal organism of this fatal disease (the Leishman-Donovan parasite) had been discovered a decade earlier; but the mode of transmission was still unknown. It was suspected generally that the transmitting agent must be an insect, but prolonged research with bed-bugs, mosquitoes, fleas, lice and ticks had yielded no convincing result. Mackie and others had observed a significant correspondence between the topographical distribution of cases of kala azar and of a particular species of sandfly, and he made an important contribution when he said in his report: "The only insect which has given any return for the work put into it is the sandfly, and I am of opinion that the relation of this insect to the disease would repay further investigation". Fourteen years later the correctness of this opinion was confirmed when intensive team-work by the staff of the Calcutta School of Tropical Medicine, supplemented by that of the Government of India's special Kala Azar Commission, convincingly incriminated the sandfly as the true vector.

Among much other outstanding work there is space to mention only the speedy and efficient manner in which Mackie, working under great difficulties of supply, established a central bacteriological laboratory in Mesopotamia in 1916 and thus ensured the prompt bacteriological diagnosis of cholera and other epidemic diseases which broke out among British troops on their way up the Tigris River to relieve Kut. The strain of the cholera vibrio which he isolated from a colleague who fell a victim to the disease was afterwards maintained as the type of the organism endemic in that part of the world. For his services in that War he was twice mentioned in dispatches and the honour of O.B.E. was conferred upon him.

After the War Mackie held in succession the posts of professor of pathology in the University of Calcutta, director of the Pasteur Institute, Assam, and director of the Haffkine Institute, Bombay. Later he officiated for a year as public health commissioner with the Government of India and for another year as surgeon general with the Government of Bombay. While holding these administrative offices he was honorary surgeon to the King and to the Viceroy. The C.S.I. was conferred upon him in 1932.

S. P. JAMES.

## Mrs. E. J. Hatfield

MANY will have learned with regret of the death of Mrs. Hatfield in early June. Those who knew her will realize that she never spared herself; after retirement she took up part-time work for the British Social Hygiene Council.

During her earlier years she studied in the University of London and at Cambridge. Some of her student years were also spent in Germany. Possessed of an open mind, she later evinced much interest in biology and psychology and followed carefully the trend of modern biological research. At the North London Collegiate School, a great many pupils passed through her classes, and all will testify to the thoroughness of her training and to the inspiration for sound work which she inculcated. While teaching, she published the well-known text-book "An Introduction to Biology".

After her retirement from teaching Mrs. Hatfield lectured for a time at one of the training colleges. At the summer schools and conferences of the British Social Hygiene Council she will be remembered for her clearly delivered lectures and wise counsel. She played a most active part in the Association of Women Science Teachers and was always in demand as a speaker at the meetings of the Association. Her position on committees, consultative or otherwise, was recognition of the opinion in which she was held by her contemporaries.

Those of us who knew Mrs. Hatfield as a friend learned to value her pleasant personality and ready smile. One could not be in her company for long without realizing her capabilities and wide cultural interests. Her outstanding characteristic was courage —the keynote of her life. Her friends and colleagues will miss very much one who possessed a fund of knowledge and a balanced outlook on life.

P. M. TAYLOR.

WE regret to announce the following deaths:

Sir Arthur Hurst, president during 1927–29 of the Section of Medicine of the Royal Society of Medicine, on August 17, aged sixty-five.

Prof. S. P. Mercer, professor of agricultural botany in the Queen's University, Belfast, and senior technical research officer of the Ministry of Agriculture, Northern Ireland, aged fifty-three.

# NEWS and VIEWS

## Agriculture at Edinburgh

THE endowment of the chair of agriculture in the University of Edinburgh was presented in 1790 by Sir William Pulteney, Bt., M.P., as a mark of his appreciation of his old University. Agriculture thus became the first chair in Edinburgh to be founded by a private benefactor, for its twenty-three predecessors had all been instituted either by the Crown or by the Town Council of Edinburgh, and it is probably the earliest foundation of its kind in any university in Britain. The present occupant of the chair, Prof. Ernest Shearer, who is also principal of the Edinburgh and East of Scotland College of Agriculture, retires after eighteen years of service at the end of this session, and the electors have selected as his successor in both posts Dr. S. J. Watson, director-in-charge of the Jealott's Hill Agricultural Research Station of Imperial Chemical Industries, Ltd.

Dr. Watson was educated at Armstrong College, Newcastle-upon-Tyne, and his agricultural interests have covered a wide field. He has been associated with Imperial Chemical Industries at first as officer-in-charge of the Animal Nutrition and Biochemistry Section, and latterly as director of the Agricultural Research Station. At Jealott's Hill his experimental work is well known to agriculturists and to scientific workers, and he has made a recognized contribution to the knowledge and practice of farm methods. His books include "The Feeding of Cattle", "The Science and Practice of Conservation of Crops" and "Silage and Crop Preservation", and his published papers cover many subjects associated with the feeding values of different kinds of crops, processes of preserving crops by drying and silage methods, and the planning of cropping.

## Geophysics at Columbia University: Appointment of Prof. Maurice Ewing

PROF. MAURICE EWING, associate professor of physics at Lehigh University, has been appointed associate professor of geophysics in the Department of Geology of Columbia University. Prof. Ewing is at present engaged in research for the U.S. Navy with the civilian rank of chief scientist, and will take up his new post at the end of the War. At Columbia, Prof. Ewing will direct graduate instruction in geophysics as part of a post-war programme of geological training and research, and will continue his investigations of the continental shelf and the ocean basins. In recent years, through the development of special equipment of his own invention, Prof. Ewing has made geophysical measurements, both from ships on the surface and from submarines, of the continental margin beneath the ocean along the Atlantic coast of North America. Through these studies it was found in 1935–38 that the slope of the outwashed sediments off the Atlantic Coast did not conform to the slope of the underlying rock floor. In war-time the experience gained from these studies has been of special value to the U.S. Navy Department, and through the co-operation of the Government Prof. Ewing has been enabled to devote all his time to geophysical research, working from the Woods Hole Oceanographic Institute, at Woods Hole, Mass.

## Employment Policy and Technical Efficiency

SOME further points in regard to the White Paper on Employment Policy were elucidated in the debate in the House of Lords on July 5 and 6. Welcoming an inquiry from Lord Barnby, Lord Woolton stated that the Government proposed to take statutory powers in order to get the statistics required. On the question of cartels and international agreements raised both by Lord Trent and Lord McGowan, Lord Woolton indicated Government concurrence in the proposal that there should be a Government inquiry on restrictive practices, and urged that the question should be considered on a factual and not an emotional basis, and from the point of view of the public interest. As was independently pointed out by Lord Wardington, such agreements embody principles identical with those enunciated in the Atlantic Charter, which advocates international agreements and co-operation and the creation of spheres of interest. On the point of technical efficiency stressed by Viscount Samuel as the most important point in the White Paper, Lord Barnby, who also raised the question of the Government's views with regard to trade associations, urged that if industry is to have efficient equipment, it requires a revision of the Factory Acts to permit the two-day shift operation of female labour. Expensive new equipment must, to carry overheads, run more than eight hours in the twenty-four. Lord McGowan referred to the growing emergence in British industry of a new social outlook, and also asked for more guidance as to the basis on which future international commercial relations are to be built. The question of controls was repeatedly mentioned, and Lord Woolton's statement that the Government is already considering the steps by which we could have an orderly unwinding of the controls reflected the practical temper of this debate, which showed a deep sense of the fundamental importance of a high standard of efficiency in British industry and that the realization of the White Paper proposals would come, as Lord Woolton said, by steady evolution and the application of modern scientific methods.

## Science in the Universities

THE report "Science in the Universities" submitted by the Association of Scientific Workers to the University Grants Committee, March 1944, which has now been published, covers very little ground that has not already been dealt with by the reports from the Parliamentary and Scientific Committee, the Association of University Teachers, or the Nuffield College statements. It is limited to consideration of the physical and biological sciences and the applied sciences immediately related to them such as are normally taught in universities, with some attention to the social sciences; within these limits, it is one of the best guides that has appeared to the ways in which the rapid expansion of scientific knowledge and its application are affecting the universities, and to the measures required to deal with the immediate problems. Among the recommendations may be mentioned those stressing practical work in the vacations as part of the training of all scientific workers, not merely those training for industry; the emphasis on the education and training of laboratory technicians, and also on the technique of teaching.

The report supports the proposal for a universities academic council to co-ordinate the development of research, and also advocates research committees in each university to watch over the development of research, and administer the Government grant for research. Stress is also laid on the extension of maintenance grants, especially in post-graduate work, and the improvement of salaries and conditions of service. The report visualizes a doubling of the 1939 undergraduate population within four years after the War. The capital cost of the accommodation required, including a possible trebling of science departments, is estimated at not less than £30 millions over ten to twenty years, with an increase in annual expenditure to £15 millions within five years and to £20 millions after ten years. Doubling the Government grant in the first full academic post-war year, with an increase to £9 millions in the fifth year, is recommended.

## Standard Frequency Broadcasts

SOME slight modifications have recently been made in the radio transmissions of standard frequencies broadcast by the U.S. National Bureau of Standards from station WWV. A new radio frequency at 2·5 Mc./sec. now operates from 23.00 until 13.00 U.T.; and the time signals have been modified by the omission of the pulse on the 59th second of every minute. The service now comprises standard radio frequencies of 2·5, 5, 10 and 15 Mc./sec., at least three of which are available at any time; standard audio frequencies of 440 and 4,000 c./sec. broadcast on these carriers; and interruptions of these broadcasts which constitute accurate time signals synchronized with the basic time service of the U.S. Naval Observatory. The time signals, which are available throughout the 24 hours, consist of pulses of 0·005 sec. duration at intervals of 1 sec. on all the carrier frequencies, and of 1-min. interruptions of the modulating frequencies every 5 min. The seconds pulses are heard as faint ticks which provide useful standards of short time intervals for physical measurements as well as serving their main function as accurate time signals. On the 59th second of every minute the pulse is omitted.

The 1-min. interval in the audio-frequency transmission is used to give the station announcement, either in Morse or (at the hour and half-hour) orally, and it also permits use of the radio frequencies uncomplicated by the presence of the low frequencies. The accuracy of all the frequencies, radio and audio, as transmitted, is higher than 1 part in $10^7$. The intervals given by the seconds pulses are correct to $10^{-5}$ sec. The 1-min., 4-min. and 5-min. intervals marked by the interruption and resumption of the modulating frequencies are accurate to 1 part in $10^7$. The Astronomer Royal's annual report remarks of these broadcasts: "A remarkable degree of agreement has been noted in comparisons of both frequency and time; as a time signal, this form of transmission appears to be capable of a very high standard of precision and to be well adapted for accurate comparisons".

## International Trade

A BROADSHEET, "Facts about International Trade" (No. 219), issued by P E P (Political and Economic Planning), describes developments since the P E P report on international trade was published in 1937, and is intended to form the starting point for a later examination of some of the main problems of post-war international trade. The main conclusions emerging from the report itself and the present broadsheet are, first, that exports are essentially a means of obtaining necessary or desirable imports: neither Britain, the United States nor any other country should export primarily to create home employment; export and import policy should be deliberately related to a nation's balance of payments and to its long-term foreign lending and borrowing. Secondly, trade restrictions and bilateralism were a symptom more than a cause of the decline in world trade after 1929; post-war policy should aim at a continuing expansion of effective world demand, making full use of the world's man-power and resources. Multilateral trade, while creating the necessary conditions for obtaining the greatest possible advantages from international trade, also heightens the economic interdependence of nations. A restoration of multilateral trade requires: (*a*) an efficient international monetary exchange clearing system in which all nations have complete confidence; (*b*) the maintenance of full employment within national economies; (*c*) the maximum attainable measure of political security. These three requirements are essential to a universal 'economy of peace'. Failing the establishment of a universal multilateral system of trade, the 'low-tariff club' represents a means by which nations most dependent on international trade can secure the benefits of multilateralism on a limited scale. 'Lend-lease' is essentially a war-time method of international exchange and is unlikely to continue after the immediate post-war period of securities; but world prosperity, like peace, is indivisible. Finally, Great Britain's major problem in foreign trade after the War is to increase her visible exports very considerably, to repair the inroads of war here and in overseas investment income, and to maintain the volume of imports vital to her standard of living.

## Soviet Academy of Sciences in Western Siberia

IT is announced in the *Soviet War News* that a new branch of the Soviet Academy of Sciences has been opened in western Siberia to direct scientific activities in the territory stretching from the Ural Mountains to the banks of the Yenisei, and from the Arctic coast to China and Central Asia. It is believed that

a promising future exists there for agriculture, forestry, fishing and coal mining; and there are large deposits of metals and raw materials for the chemical industry. Long before the outbreak of war, the Soviet Government had made detailed plans for the development of Western Siberia; the War has given a great impetus to the process of industrialization. Many of the factories, colleges and scientific research institutions evacuated to the territory from the danger zones have already returned to their homes, but not without leaving behind important traces of their activities, as well as a proportion of their staffs to continue the work begun in Siberia.

The West Siberian branch of the Academy incorporates the Mining, Engineering and Geology Institute, the Chemico-Metallurgical Institute, the Power and Transport Institute and the Medical and Biological Institute; Novosibirsk has been chosen as its seat; and it will also have offices in Tomsk and Omsk, as well as in the new industrial towns which have sprung up during the last twenty-five years. Typical of these are Kemerovo (chemical and coal industry), Prokopievsk (coal), Stalinsk (metallurgical industry and mining) and Barnaul (centre of the Altai region). Prof. A. Skochinsky, a specialist in mining engineering, is head of the newly formed branch.

## British Film Institute Summer School

A COURSE on visual education was organized by the British Film Institute at Bangor during August 19–26. Among a wide range of topics discussed, very useful contributions were made by Mr. Geoffrey Bell of the Shell Film Unit who discussed "The Scientific Film" and Mr. Neilson Baxter, of the same Unit, who dealt with "The Documentary Film". Both argued that the scientific, realist approach to a subject so characteristic of the documentary group of film-makers is in essence also the proper characteristic of an educational classroom film, as well as being useful for enlarging the child's general knowledge of his environment. Other speakers were Mr. G. P. Meredith, lecturer in visual education at the University College of the South-West, Dr. Winifred Cullis, who made a plea for an increase in the number of films for teaching physiology, and Lieut. M. G. Bowden of the U.S. Army, who gave the conference an account of the extent to which visual aids were used in America. The conference was attended by Polish, Dutch and Canadian representatives, as well as by English teachers and film-makers.

## Crop-cutting Survey of Wheat in the Punjab

PRELIMINARY results have just reached Great Britain of an interesting example of random stratified sampling on the grand scale, devised by Dr. P. V. Sukhatme, statistician to the Imperial Council of Agricultural Research, New Delhi, and carried out by the Department of Agriculture of the Punjab. By sampling a hundred out of the total of nine million acres under wheat, the net out-turn of that crop for twenty-seven of the twenty-nine districts of the Province is estimated at 3,448,700 tons, with a standard error only just over 1 per cent. The cost of the survey scarcely exceeded Rs. 1,000 per district.

Uniformity of practice was obtained by central training of the senior staff concerned in all the details of the experiment, and also by central selection of the 748 villages (about 2 per cent of the total number available) used for the scheme. These were, for each district of the Province, proportionate in number to the area under wheat, but equally distributed among the tehsils of the district, and randomly within each tehsil. Within each village three fields were selected (since previous experimentation had shown little difference between the variation between villages and that between the fields of a village, and practical considerations of time, labour and cost counselled concentration of fields within a village), and within each field one plot of 1/20 acre (the variation between plots in a field being less than that attributable to either source just mentioned). Selection of the fields in villages and of the plot in each field was by use of random numbers supplied by the centre, which was able to check the process. Harvesting, threshing, winnowing and weighing were normally completed in one day. The final estimate includes adjustments for 'driage' owing to the divergence of this procedure, necessary for accuracy and speed, from the general practice (which allows a week or two for drying between harvest and threshing), and also for the different yields of wheat sown pure or mixed with other crops.

## Improved Use of Daylight

Two useful recent publications deal with the more effective use of natural daylight. "The Natural Lighting of Houses and Flats with Graded Daylight Factor Tables", by T. Smith and Miss E. D. Brown of the National Physical Laboratory (London: H.M. Stationery Office, 4*d*. net), gives guidance in the choice of window dimensions for houses and flats. The penetration of daylight through a window is discussed, and tables are given from which the penetration of daylight for different window dimensions may be assessed. These tables are for daylight factors of 2, 1 and 0·5 per cent respectively. "Natural Lighting", Lighting Reconstruction Pamphlet No. 4 issued by the Illuminating Engineering Society (1*s*.), deals with the subject in a descriptive manner, and shows particularly the benefit derived from high windows and the suitable planning of buildings. In the most favourable circumstances, a daylight factor of 5 per cent may be attained at the working table, and in no case should the daylight factor be less than 0·2 per cent.

## Announcements

MR. R. H. HILL, secretary of the Bodleian Library, has been appointed librarian and secretary to the Trustees of the National Central Library, in succession to Dr. Luxmoore Newcombe, who retires at the end of the year.

BOOKS and prints relating to various States of Central and South America, the West Indies and the Antarctic, as well as some rare old maps are the subject of Catalogue 671, issued by Messrs. Francis Edwards, Ltd., Marylebone High Street, London, W.1. The catalogue includes several rare items: a complete set of the *Challenger* results in forty-one volumes; J. Colnett's "Voyage of Whaling and Discovery" (1793–94), with his manuscript journal of the same date; the manuscripts of several of Cunninghame Graham's books; Grynaeus' "Novus Orbis", with the rare map of 1532; the first Latin edition of Munster, "Cosmographiae Universalis" (1550); "Purchas his Pilgrimes" (1624–26); Apian's map of America (1520); and Arrowsmith's chart of the Pacific (1798).

# LETTERS TO THE EDITORS

*The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.*

## Marine Biological Research in Great Britain

THE letter published in *Nature* of July 29 from Prof. F. E. Fritsch opens an important subject which has been in the minds of a number of zoologists during the past few years, and it is one in connexion with which some of us would be extremely glad to see action taken on the lines which Prof. Fritsch indicates. Whatever this action may be, it is essential to realize from the outset (as Prof. Fritsch does) that nothing short of one or more teams of full-time workers will meet the case adequately; the problems involved are too numerous and too complex to make a part-time attack on them any longer profitable. One can envisage valuable part-time assistance for the team, but a nucleus of full-time workers is indispensable.

It is not clear whether Prof. Fritsch has more in mind the benthic communities which exist between tidemarks, or those below tidemarks—presumably both. In fact, the need for new advances is very great in both fields, but the methods required for offshore work are very different from those appropriate between tidemarks, and undoubtedly different groups of workers should tackle the two aspects. As my own particular interest is in the intertidal zone, I should like to offer a comment referring to this belt, leaving the development of the offshore theme to others more competent to deal with it.

My own approach to British shore ecology has been through foreign waters, beginning with the Great Barrier Reef Expedition in 1928–29, extending to other tropical coasts, and including ten years in South Africa, where one sees a complete transition from sub-tropical to almost sub-antarctic conditions. During the years 1931–40 I was able, with the assistance of a dozen collaborators, to carry out a preliminary general survey of the South African coast, covering a distance of more than 1,800 miles, which was visited at about a hundred localities altogether[1]. Having done this, we naturally wished to compare our results with those arrived at in other countries, but it is very striking how little there is with which *direct* comparison is possible, despite the existence of a considerable literature. We reach, therefore, the rather astonishing conclusion that the intertidal region of South Africa (almost unknown, ecologically, in 1930) is probably, at the moment, better known, in its broad outlines, than any stretch of coast of comparable length in the world. The work from another area most nearly comparable with it is that of Fischer-Piette from the French and Channel coasts; one can piece together a rather imperfect picture for the coasts of North America (especially the Pacific coast); there are the accounts of coral reefs; but many regions of the world are unknown altogether, or known from one or two isolated papers only. A *general* picture of the tidal belt round the British coasts does not exist, in spite of our detailed knowledge of particular localities. This will be partly remedied so far as Algæ are concerned when surveys carried out during the present War are published; for animals there is an immense amount of work still to be done.

It is important to emphasize, in this connexion, that we shall never get a satisfying picture of the British coasts until we can fit them, in their due relation, into the larger picture of the world as a whole. Advances in the ecology of large areas have affected the land, fresh water, and the oceans much more than the tidal region; and a preliminary general statement covering intertidal biology in the world as a whole is very much needed. The need for relating Britain to this general picture can best be illustrated by a specific example. The South African survey mentioned above began as an attempt to solve the problem presented by the action of ocean currents on the coasts of the thirty-mile-long Cape Peninsula, a region of special zoo-geographical interest. It was immediately discovered, however, that this problem was literally insoluble until some sort of picture of the South African coast as a whole had been obtained; once the latter was available, the Peninsula became intelligible. Similarly, Britain will probably never become fully intelligible until its relation to the rest of the world is better understood than at present.

I do not wish to imply that future developments in Britain need necessarily repeat the particular type of work already done in South Africa. It has been pointed out that geographically Britain is a much more difficult and confused region than South Africa, unlikely to give clear-cut results, and that the amount of work needed to obtain the results would be out of proportion to their value. However this may be, it will be agreed by most people that a great deal of further work of *some* types is needed on the British coasts.

I should like, therefore, to develop Prof. Fritsch's thesis to this extent, that we need three things, involving three different modes of attack, and each of them demanding a team of full-time workers. These are (*a*) further work on the British coasts between tidemarks; (*b*) further work on the continental shelf of the British region, below tidemarks; and (*c*) an attempt to make a preliminary world-statement, based on a carefully selected series of samples, all seen by the same workers. As a matter of fact, there exist fairly detailed plans covering certain parts of the programme just outlined, and it would seem desirable that those most immediately concerned should consult together as to the best means of giving effect to such plans.

University College,
Aberystwyth.

[1] A general account of this survey is in the press and due to appear in the next issue of the *Annals of the Natal Museum*; earlier parts of the work are described in a series of papers in that journal, and also in *J. Linn. Soc.* (*Zool.*), *Trans Roy. Soc. S. Africa* and other periodicals.

---

WE have read with interest Prof. F. E. Fritsch's letter on marine biological research in Great Britain[1], in which he stresses the need for the co-operation of botanists and zoologists in the investigation especially of marine benthos and refers to the difficulties and limitations experienced by investigators in universities at a distance from the sea.

We should welcome the new developments which Prof. Fritsch envisages as desirable at Plymouth. It seems to us that, whether or not these materialize,

there is ample room also for similar developments elsewhere. In particular, centres for 'academic' research, complementary to, and co-operating with, Plymouth, would find adequate opportunity for useful work. We have had such a centre in view in planning our development policy here and in preparatory work that has been in progress for a number of years.

In Bangor we are exceptionally favoured, in close proximity to a littoral fauna and flora which, both in variety of habitats and in wealth of interesting species, must be judged to be among the richest in the kingdom. Certainly no other university institution in Great Britain is better provided in this respect at its very doors. Consequently marine biology has always taken a prominent place in our university courses. A vacation course in marine zoology, which draws students from many other universities, has been held annually for the last thirteen years. We have regarded marine biology, moreover, as a subject which should have high priority in the promotion of research in this College.

Much is already known about the fauna of this area, as can be seen from a glance at the pages of almost any standard systematic work on British marine animals—for example, Alder and Hancock's "British Nudibranchiate Mollusca"; moreover, the pioneer work of Sir William Herdman and his collaborators provides a preliminary survey of the fauna. The staff of the Zoology Department has been for a number of years compiling a fauna list from these records and, with the help of a number of visiting workers, has extensively added to it. Though much remains to be done before this list can be regarded as sufficiently complete for publication, we already have a good working knowledge of the principal species and their distribution.

Parallel information on the marine flora has been accumulated by members of staff of the Botany Department, supplementing the earlier records of Prof. R. W. Phillips, whose algological library is housed in the Department. The work done by Phillips and Lloyd Williams created a local tradition which we feel should be maintained.

Prof. Fritsch has stressed the importance of the benthic diatoms. Other components of the microflora may also prove of great importance. The study of the marine microflora is a natural extension of a study of the freshwater microflora of this district which is already being carried on intensively.

Aware of the opportunities our situation offers and conscious of the need for providing special facilities for the study of marine biology in at least one of the constituent colleges of the University of Wales, the Council of this College has included among its principal post-war aims the founding of a marine biological station at Bangor, to serve the needs of academic research and teaching within the Principality. We hope that this might also serve in part the wider need to which Prof. Fritsch has directed attention.

To be reasonably useful and efficient, such a station as we plan would require a team of workers covering the various aspects of marine biology, both floral and faunal. The advantage of founding such a station in close conjunction with our existing departments is obvious, since the staffs of these departments would go some way towards providing the nucleus of a team. We hope, too, that we shall have the co-operation of our colleagues who are interested in marine biology from the other Colleges of this University.

---

I WOULD like to endorse Prof. F. E. Fritsch's letter in *Nature* of July 29 on this subject. It is regrettable that a country such as ours with many suitable habitats for marine algæ should lag behind Continental countries in the study of this particular group of plants. Both the last and the present Wars revived an interest in the marine algæ, and the present War has certainly shown how ignorant we still are about many fundamental facts of the life-history of seaweeds. Some of these problems are now being solved and the gaps in our knowledge closed, but it is important that the work should not cease when the War ends. The establishment of a centre for this work is long overdue. At the recent annual meeting of the Marine Biological Association, it was hoped that at least one if not more whole-time workers on marine algæ might be appointed at the end of the War. This may well be a start in the direction indicated by Prof. Fritsch.

As regards the establishment of centres outside Great Britain, some time ago I advocated in *Nature*[1] the establishment of a research station in the West Indies with an algologist on the permanent staff. This station I suggested should be administered by British universities. Since then, the Commission on Higher Education has visited the West Indies and it is going to propose the establishment of a university college in the islands. A research station such as I envisaged may well form part of such a college. It remains to be seen what the Commission suggests in its report.

## Action of Pepsin on Acylated and Non-acylated Cysteine- (Cystine-) Tyrosine Peptides

IN connexion with some projected immunochemical work, we have recently had occasion to synthesize cysteyl- and cystyl-tyrosine and tyrosyl-cysteine and -cystine. Since these peptides represent a type which has not hitherto been available, it was considered worth while to study the action on them and their N-carbobenzyloxy derivatives of crystalline pepsin.

So far the only synthetic substrates known to be attacked by pepsin are certain derivatives of peptides containing tyrosine or phenylalanine and glutamic acid, in which the amino group of the aromatic amino-acid is combined with the α-carboxyl group of an acylated glutamic acid[1]. The peptic hydrolysis of these substrates occurs most rapidly at $p$H 4·0 and scarcely at all below $p$H 2·0; no hydrolysis of the free peptides takes place and the reaction is further inhibited if the free carboxyl group of the glutamic acid residue is blocked. On the basis of these observations, Bergmann[2] has drawn the general conclusion that hydrolysis by pepsin is conditional on the absence of a free amino group from the immediate

neighbourhood of the linkage attacked, and that a substrate for peptic action must contain more than one free carboxyl group.

Some of our own observations on the cysteine-(cystine-) tyrosine peptides are given in the accompanying table, from which the following conclusions may be drawn: (1) This group of compounds includes some which offer good examples of simple synthetic substrates for peptic action. (2) The action of pepsin on these substrates is much more marked at *p*H 4·0 than at *p*H 1·8, although in two cases at least it is still significant at the latter reaction. (3) While the N-acylated peptides are more rapidly hydrolysed, the action of pepsin extends in this series to the free peptides, which thus represent the first true peptides shown to be attacked by this enzyme.

PERCENTAGE SPLITTING OF ACYLATED AND NON-ACYLATED CYSTEINE-(CYSTINE-) TYROSINE PEPTIDES BY CRYSTALLINE PEPSIN IN 48 HR. AT 37°.

| | *p*H 4·0 | *p*H 1·8 |
|---|---|---|
| A. ACYLATED PEPTIDES | | |
| N-Carbobenzyloxytyrosylcysteine .. .. | 39 | 10 |
| N-Carbobenzyloxytyrosylcystine .. .. | 7 | 0 |
| N-Carbobenzyloxycysteyltyrosine .. .. | 53 | 32 |
| N-Carbobenzyloxycystyltyrosine .. .. | 21 | 6 |
| N-Carbobenzyloxy-S-benzylcysteyltyrosine .. | 26 | — |
| B. NON-ACYLATED PEPTIDES | | |
| Tyrosylcysteine .. .. .. .. .. | 22 | 8 |
| Tyrosylcystine .. .. .. .. .. | 5 | 8 |
| Cysteyltyrosine .. .. .. .. .. | 31 | 21 |
| Cystyltyrosine .. .. .. .. .. | 5 | 0 |

In view of these results, it seems that the generalization of Bergmann regarding the necessary conditions for peptic action requires modification. In none of our cysteine derivatives (which are the more readily hydrolysed) is there more than one free carboxyl group, and the hydrolysis of the free peptides is unmistakable; it is especially noteworthy that one of the free peptides (cysteyltyrosine) is significantly hydrolysed at *p*H 1·8, a reaction at which the amino group will be charged.

A further point which seems to us to be of interest emerges from our experiments. It will be noted that the rate of hydrolysis is conspicuously greater, both with the acylated and non-acylated peptides, when these are in the reduced form; that this increased susceptibility to peptic action is due to the presence of free –SH groups is further shown by the fact that blockage of the –SH group of N-carbobenzyloxycysteyltyrosine with a benzyl residue reduces its rate of hydrolysis to that of the corresponding cystine derivative. This greater susceptibility of the cysteine derivatives to peptic hydrolysis may be related with the facts that: (*a*) pepsin attacks proteins more vigorously when they are in the denatured than in the native state; and (*b*) denaturation of proteins is accompanied by the appearance of –SH groups. Taking into account our own observations and the known fact that free tyrosine can be liberated from proteins by pepsin, it seems not unlikely that at least one point of attack of a denatured protein by this enzyme may be a cysteyltyrosine or tyrosylcysteine linkage.

A complete account of the synthesis of the peptides described above and of the enzymic experiments is being submitted for publication elsewhere.

# Effect of Adrenalectomy and Anterior Pituitary Injections on Mammary Development

THOUGH mammary growth has been stimulated experimentally with desoxycorticosterone[1,2], the possible significance of the adrenal cortex in normal and experimental mammary development has scarcely been investigated from other aspects. Elucidation of the role of the adrenal cortex in mammary development assumes added importance in view of the claim that the agents directly responsible for the growth of the mammary gland are two mammogenic hormones, secreted by the anterior pituitary, which cause growth of the mammary ducts[3] and alveoli[4] respectively. The possibility must be considered that the mammogenic action of anterior pituitary extracts may be mediated, wholly or in part, by the adrenals. We have accordingly begun a study of the effect of adrenalectomy on the mammary gland in relation to the mammogenic action of the anterior pituitary. A preliminary account of the results so far obtained may be of interest.

In this study we have used a fresh saline extract of ox anterior pituitary[5], for the gift of which we are indebted to Prof. F. G. Young. Using immature gonadectomized rats, it was found that this extract evoked a striking increase in the degree of arborization of the mammary duct system. To use a rough analogy, whole mounts of the mammary glands of control and injected rats were reminiscent of the appearance of a deciduous tree in winter and late spring respectively.

Having established that this pituitary extract possessed marked mammogenic activity, an experiment involving adrenalectomy was set up. This involved four groups, each of 5 male rats, and four of 6 female rats, all gonadectomized at 27 days. Two groups of either sex were adrenalectomized at 74–85 days, and one group of adrenalectomized and one of non-adrenalectomized rats of either sex received ten daily subcutaneous injections of 0·4 ml. anterior pituitary extract (equals 100 mgm. fresh tissue). At the end of the injection period, whole mounts (hæmatoxylin) of all the mammary glands, normally 10 in the male and 12 in the female, were prepared and the glandular areas measured.

The glands were examined under the low power (× 15) binocular and each assigned a score on a subjective scale on the basis of the degree of the arborization of the duct system, the number of lateral buds and the presence of the deeply staining club-shaped end buds characteristic of actively growing ducts. The results indicated once again that in both sexes the pituitary extract increased the complexity of the duct system; only in males, however, was there any evidence of a decreased effect in adrenalectomized rats. In uninjected animals, in contrast to previously reported experiments[6,7], adrenalectomy had no discernible effect on mammary structure. In a majority of the non-adrenalectomized males injected with anterior pituitary, the mammary ducts, though not very complicated, were dilated and lined with deeply staining and distended structures which appeared to be alveoli; in contrast, the comparable group of adrenalectomized males showed thin, branching duct systems. The appearance of the former glands was reminiscent of that of glands described by Astwood *et al.*[8] in normal adult male rats or in gonadectomized immature rats of both

* Obtained from an analysis of variance.

sexes treated with androgens. It seems possible that in males, at least, the pituitary injections evoked the secretion of adrenal cortex steroids with androgenic activity.

The mammary area data were summed for each rat and the results for each sex subjected to an analysis of variance. For help with the statistical analysis we are indebted to Dr. K. L. Blaxter and Dr. K. Mather. The mean values for each group and the standard errors are given in the accompanying table. In both sexes the total mammary gland area (which was greater in females than in males) was significantly decreased by adrenalectomy ($P = 0{\cdot}02$ for males and 0·03 for females), a result not in agreement with the only two previous reports[6,7] we have been able to find on this subject. The results also suggest that, in females, anterior pituitary treatment increased the mammary gland area in the presence of the adrenals but not in their absence; the probability ($P = 0{\cdot}06$) was, however, not very great, and this conclusion cannot be taken as established unless the results are confirmed by those of other experiments, at present in progress, in which, it is hoped, conditions will be more favourable for the demonstration of the expected effects. In males, there was no evidence that the anterior pituitary extract had any effect on mammary gland area, either in the presence or absence of the adrenals.

The implication of the foregoing results is that the intervention of hormones of the adrenal cortex must be taken into consideration in relation both to normal and experimental mammary development.

We are indebted to the Agricultural Research Council for a research grant to one of us (A. T. C.) and to Dr. S. K. Kon for facilities for working with rats.

## Effects of Administration of Trinitrotoluene

Several workers have shown that the administration of aromatic nitro- and amino-bodies to the human being results in cyanosis and porphyrinuria, indicating a disturbance of pigment metabolism. Trinitrotoluene (T.N.T.), for example, may damage the liver and cause anæmia, jaundice and porphyrinuria, and serious effects on the health of munition workers can result. A short while ago, we were investigating the action of T.N.T. upon the hæmopoietic system in healthy rats and, as its metabolism in the body has now been studied extensively[1], we think it is of interest to record some of our results here.

Groups of three male albino rats (150–200 gm. each) were maintained in metabolism cages on a daily fixed weight of porphyrin-free diet in a paste form as used in earlier experiments[2]. The animals were allowed free access to water and their urines were collected in flasks containing toluol. Every two days the urines were collected and transferred to volumetric flasks and made up 100 ml. with the cage washings. The improved Webster test for T.N.T. derivatives[3] was performed on each, and the porphyrin content in the remainder estimated using Rimington and Hemmings' technique[4]. After three control periods each of two days during which excretion values per 100 gm. body weight became fairly constant, three groups of rats were injected subcutaneously with varying doses of a suspension of T.N.T. in 2 per cent acacia mucilage in tap water. Each dose was given per body weight. Injections of the same dose were given every two days in alternate flanks of the back. Each animal received nine injections. One control group of rats received a corresponding dose of mucilage of acacia only. All the conditions were standardized so far as possible.

After one injection, the urines from the rats receiving T.N.T. were red, now shown to be probably a derivative of 2 : 4 : 6-trinitrobenzyl alcohol[1], and later the acid shakings of the ether extracts became light brown. Unidentified brown pigments often accompany increases in porphyrin excretion. Throughout the experiments, coproporphyrin only was identified in the urine by measuring the absorption graph in 25 per cent hydrochloric acid. It was probably the Series III isomer, though this was not confirmed. Group I receiving 200 mgm. T.N.T. per kgm. showed no significant change in urinary porphyrin in the time studied; mean total urinary porphyrin per 100 gm. body weight before injection was 4·6 μ gm. per 2 days, and after dosage was 5·5 μ gm. Group 2 receiving 400 mgm. T.N.T. per kgm. showed an increase after six injections (5·8 μ gm. to 11·3 μ gm.), while Group 3 receiving 600 mgm. T.N.T. per kgm. showed porphyrinuria after four injections (4·0 μ gm. to 11·8 μ gm.). Liver damage was noted in this latter group by taking sections and also staining for iron. The stomachs of these rats were very brown and blown up. The modified Webster's test was completely negative throughout, confirming previous views that porphyrinuria is not related to the presence of T.N.T. in the urine[5]. Values of urinary porphyrin for the control group were 6·1 μ gm. before injection and a mean of 6·9 μ gm. following acacia dosage.

Four further groups of adult male albino rats (150–200 gm. each) were similarly treated but received the dosage of T.N.T. by stomach tube. The

onset of porphyrinuria was expected to be quicker. Group 1 showed no change in urinary porphyrin, but Groups 2 and 3 showed extensive porphyrinuria following two injections of 400 and 600 mgm. T.N.T. per kgm. respectively (1·9 $\mu$ gm. to 6·3 $\mu$ gm., and 5·4 $\mu$ gm. to 15·5 $\mu$ gm.). The acid shakings of the urines of these two groups were dark brown. The modified Webster's test was again negative throughout, and the control group showed no change in porphyrin output.

The results show that the absorption of T.N.T. in the rat takes place more rapidly in the stomach than by subcutaneous injection; the toxic effects such as porphyrinuria and liver damage follow more quickly. A red urine was not produced by administering doses of 2 : 4-dinitrotoluene or of *p*-nitrotoluene, and it is suggested that three nitro-groups are necessary for the formation of the red colour.

## Birds and Butterflies

CAPT. C. R. STONOR, under this heading in *Nature* of July 15, p. 80, says that he "did not see a single bird, of any species, catch or chase a butterfly" during a month in rain-forest in South India. One can only comment that abundant evidence was provided from tropical Africa by the late C. F. M. Swynnerton. This outstanding field naturalist, well known for his work on tsetse control, could not find time, while engaged in this work, to sort out the massed observations for publication. After his lamented death in an aeroplane crash, it fell to my lot to edit some of his material[1].

It is interesting to note that some of the subjects of these records were the same families—or even genera—of birds as were seen by Capt. Stonor not catching butterflies; for example, rollers, bee-eaters, drongos. Capt Stonor especially mentions the "large racquet-tailed drongo" in his negative evidence, and I would refer him, and readers, to my note[2] in which I showed photographs of two butterflies from different parts of the range of this bird, each bearing a clearly imprinted mark on a wing closely corresponding with the imprint of the bill of a specimen.

Not only does the study of such beak-marks provide evidence that butterflies are attacked but also, as I showed in 1941[3], it has provided significant evidence that the attacks are less destructive of the aposematic ('warningly coloured') species which serve as models for mimicry than those mimicking them. Regarding Capt. Stonor's statement that he saw no beak marks, I may perhaps be excused for saying that they are not always so obvious as those I have mentioned above, and particularly in "tattered specimens" which have been mauled and rubbed so that the density of the scaly covering is reduced; experience in close study of 'set' specimens is needed.

The statement that "the butterflies seldom flew higher than four or five yards from the ground; while most of the insectivorous birds . . . feed twenty feet up at the least", presumably means that it is considered that at high levels there are no butterflies to be attacked. This, however, is far from being the case. It is recorded by Beebe[4], Hingston[5] and Chapin[6] that the fauna of the tree-tops is distinct from that at lower levels, and Hingston particularly notes "Butterflies are commonly seen fluttering over the canopy. Some species probably never come to earth." Most butterfly collectors in the forests must have had my exasperating experience of seeing desirable specimens flying around and settling on the tops of trees in flower. The oriental butterfly *Eriboea schreiberi* Godt. is particularly interesting in this connexion. It is stated by Fruhstorfer[7] to be 'extremely rare' (that is, in *collections*) and he also says "It is also frequently stated that single wings are found from which we may conclude that *schreiberi* is very much pursued by birds". The same curious fact is the subject of comment by Poulton in his notes attached to G. A. K. Marshall's records of attacks on butterflies[8].

## A New Species of Amœba: *A. kerrii*

SINCE the publication of full details with relevant plates and drawings will necessarily be long delayed, the following account of a new species of amœba belonging to Schaeffer's genus Metachaos, isolated from some water-weeds collected on the shore in front of the Marine Biological Station of Keppel by Miss Maureen McAlister in 1939, and now under cultivation in Notre Dame Laboratory, will serve as a preliminary notice to other workers.

Species of the genera Chaos and Metachaos are distinguished by their cytoplasmic characteristics or by details of their life-history. This amœba, named in honour of Sir John Graham Kerr, who first emphasized the urgent necessity of research on an organism so universally used for education in biology, is easily identified in its fully adult and senile stages by its dusky appearance when viewed over a black background by reflected light, this dark colour being due to the extraordinary abundance of crystals which distend the cytoplasm and completely mask the presence of the nutritive spheres. The nucleus by contrast looks almost like a vacuole as it is rolled about in the cytoplasm.

Young adults and adolescents are much clearer and more like the typical appearance of most of the free-living, large amœbæ. Pure-line cultures of *Amœba kerrii* are easily established, the creature feeding on rotifers, ciliates and flagellates. Wheat grains form a suitable pabulum.

Fission divisions occur in adolescent and in young adults, but not in old or senile adults, once in three

days, at a suitable temperature. The line of demarcation between two daughter amœbæ travels down from north to south of the fission sphere (= the form assumed by the dividing amœba), which remains firmly in contact with the substratum during the whole process of division. In this it resembles *A. proteus* γ and *A. discoides*, and differs from *A. lescheræ*. Division of the nucleus is mitotic and takes place within the nuclear membrane; the chromosomes are small and numerous. The telophasic stages are semi-elliptical in outline, in contradistinction to those of *A. lescheræ*, which are more or less triangular. The ectoplasm, which has no longitudinal folds, is tougher than that of the other amœbæ we have investigated. This is an especially useful characteristic for the study of the developing young, permanent preparations of which are, in consequence, more readily made.

The resting nuclei of both adult and developing amœbæ are of the typical form. In the former, a central karyosome suspended in an achromatic network is separated by a clear area from the region of the regularly disposed chromatin blocks lying just under the nuclear membrane. A variety of form consequent upon the fact that the nucleus is rolled about into all sorts of positions by the surrounding cytoplasm may be seen when large numbers of *A. kerrii* are fixed and stained.

The reproductive cycle commences with the emission of chromidia from the nucleus of an adult amœba into the surrounding cytoplasm. Each chromidial mass becomes the rudiment of the nucleus of the new amœba, which is differentiated in the agamont and becomes an encysted agamete. Hundreds of these are shed into the surrounding medium, where they remain for a varying period of time. Hatching out of the young amœba, which is only just visible under a ⅙-in. objective, is more easily observed in winter. A limax form is that most often assumed by the growing young amœba, the nucleus of which is easily visible. In about eight months the whole life-cycle of *A. kerrii* is completed.

## Boundaries of Space and Time

IT is with some diffidence that I venture to comment on the very abstruse issues raised by Prof. Dingle in his Halley Lecture (*Nature*, **153**, 731, 758; 1944) but there is an aspect of the matter to which it seems worth while to direct attention.

The theory of relativity tells us that observable space has a boundary, the extent of which can be approximately estimated, and that any events which may take place, or which may have taken place, at or beyond this boundary are unknown and unknowable. It would also appear that the interpretation of events which may appear to occur near the boundary must be indeterminate, because it is impossible to say to what extent they may be influenced by events or conditions beyond the boundary, of which, it is agreed, we can have no knowledge. Moreover, it may be suggested that this doctrine of a boundary to the observable universe is reasonable whether we accept the other implications of the theory or not.

The boundaries of comprehensible time, past and future, are not known with the same precision as the boundaries of observable space, but it is reasonable to postulate that such boundaries must exist, and that any discussion of events which lie beyond these boundaries is meaningless.

The purpose of the present letter is to point out an important consequence which follows from these postulates: when we are discussing events lying within these boundaries of space and time, we are not entitled to introduce into our argument any assumptions as to conditions at the boundaries or beyond them. Thus we are not entitled to favour theories which enable us to extend the boundaries of time to infinity any more than we are entitled to favour theories which postulate an infinite extension of space. Provided that the boundaries of time permitted by a theory are sufficiently extensive to be consistent with observed facts, no more can be demanded of it.

There is also a further point. We live in a world of change, but there are certain properties of the universe as we know it which appear to be constant in time. It must be remembered, however, that our observations extend over an interval of time which is infinitesimal compared with the periods of time which we are wont to discuss, and we do not therefore appear to have any reliable means of determining whether these apparently constant quantities are in fact constant, or whether they are slowly variable over long periods, and if so in what sense. Where two or more theories are consistent with the observed facts and differ only in respect of the conditions which they involve at the boundaries of space and time, the selection of one theory or another would appear to be entirely a matter of convenience.

K. E. EDGEWORTH.

Cherbury,
Booterstown,
Co. Dublin.

THE theory of relativity tells us that observable space may not be infinite in extent, but it does not postulate a boundary; "finite but unbounded" is the usual phrase. The theory gives no support to the idea that observable events can be influenced by conditions outside the region of possible observation, nor does it set any limits to time. In this respect time differs from space. The last paragraph of Colonel Edgeworth's letter is perfectly correct in principle, but the range of our present knowledge can scarcely be called infinitesimal. A quantity may change so slowly as to appear constant, but the progress of science consists partly in extending the range of observation so as to detect such changes; the slowing down of the earth's rotation, and the reddening of nebular light, however it be interpreted, are examples. It is always possible, of course (unless constancy is postulated by definition), to say that an apparently constant phenomenon is changing too slowly for detection; but any theory which included this assumption would probably give some indication of the rate of change, and further knowledge would enable us to determine whether the assumption was valid. The question of retaining the theory would then be decided on grounds other than convenience.

# ROYAL SOCIETY OF CANADA

## ANNUAL MEETING

THE 1944 meeting of the Royal Society of Canada was held at the University of Montreal during May 29–31 under the presidency of Mgr. Olivier Marault, rector of the University.

New fellows presented at the first general meeting included the following in the scientific sections: Section III (Chemical, Mathematical and Physical Sciences): R. C. Dearle, G. S. Field, John T. Henderson, G. de B. Robinson, W. Ure; Section IV (Geological Sciences): J. W. Ambrose, G. V. Douglas, H. B. Yates; Section V (Biological Sciences): J. A. Anderson, W. V. Cone, G. E. Hall, W. F. Hanna, Georges Maheux, D. S. Rawson. Lieut.-General A. G. L. McNaughton, who had been elected an honorary fellow in 1941, while he was absent from the Dominion as Commander-in-Chief of Canada's Army Overseas, was also presented.

The Society's medals were presented at the evening meeting on May 29 as follows: Flavelle Medal to Prof. Velyien E. Henderson, professor of pharmacy and pharmacology in the University of Toronto, in recognition of contributions to knowledge in the fields of pharmacology, physiology and therapeutics, including the discovery of the anæsthetic properties of cyclopropane; Henry Marshall Tory Medal to Prof. Frank Allen, professor of physics in the University of Manitoba, for his contributions to the subjects of optics and acoustics and especially to a border region of physics and physiology; Tyrell Medal to Prof. Harold A. Innis, professor of political economy in the University of Toronto.

Following the presentation of the medals, the presidential address "Montréal: une Synthêse" was delivered by Mgr. Marault. A popular lecture on "War, Peace and Commerce" was given on the evening of May 30 by Dr. B. K. Sandwell.

In Section III, the presidential address by Prof. T. Thorvaldson, professor of chemistry in the University of Saskatchewan, dealt with "The Solid State". It reviewed the various theories of chemical reactions in the solid state and the experimental evidence in support of them. This was followed by a symposium on the same subject, in which Prof. M. A. Peacock described the methods of identification of solid phases by crystallographic means and Prof. E. F. Burton showed some recent photographs taken with the Toronto electron microscope of the forms of solid particles of ultramicroscopic dimensions. The final paper of this symposium, by Dr. G. S. Whitby, was on rubber, and described the chemical constitution and related physical properties of several of the new artificial rubbers now being produced.

Among the thirty-two other papers presented to the Section, mention may be made of one by Prof. Frank Allen, in which results of experiments on the sensitivity of the colour sensations were described. He finds that when the right eye, for example, is adapted to red light, the red sensation is reduced, but in the left eye all three sensations (red, green and violet) are enhanced. If the eye is rested after adaptation for three minutes, a reversal in sensitivity occurs. There is thus an oscillation of sensitivity. A paper on further simplification in thermodynamical calculations along lines previously developed was read by Prof. A. N. Shaw. Dr. J. A. Pearce and E. C. Walker reported the orbital elements of λ Andromedæ based on a series of measurements made on high-dispersion spectrograms taken at Victoria, B.C. Dr. E. C. Beale discussed results which indicate that some new molecular absorption lines recently discovered show characteristics closely similar to atomic lines. It is suggested that their probable origin is to be found in the solid particles responsible for general absorption in interstellar space, and that laboratory investigations of the absorption spectra of such particles as are likely to be present in interstellar space might be fruitful in their identification. A new mechanical height computer for *radio sonde* observations was described and shown by Dr. W. E. Knowles Middleton. Dr. J. A. Pearce, of the Dominion Observatory, was elected president of the Section, and Prof. C. T. Sullivan, Repath professor of pure mathematics at McGill University, vice-president.

In Section IV, the presidential address by Dr. W. A. Bell, palæobotanist of the Geological Survey of Canada, dealt with the use of some floras in Canadian stratigraphy. Fossil floras have proved very useful in subdividing the very thick carboniferous sediments of the Maritime Provinces into six groups, of which three are Mississippian and three Pennsylvanian. The use of the terms Mississippian and Pennsylvanian is more appropriate as regards major floral and tectonic events of the Acadian province than Lower and Upper Carboniferous. The former terms are not synonymous with the latter, for the Mississippian terminated in an early part of Upper Carboniferous time, as in the Mississippian valley region. The group subdivision established mainly on floral evidence is apparently the most natural one, for it is corroborated by tectonic events. Coal formation was not confined to one age as formerly assumed, but took place locally in the Pennsylvanian in each of the three ages represented by the groups of strata.

Nineteen other papers on geological and mineralogical researches were presented. Dr. Madeleine Fritz, Royal Ontario Museum of Palæontology, reported the recent discovery of the bryozoan species *Trachytoechus moniliformia* Fritz, n.sp. in the Gaspe sandstone of Lemieux Township, Gaspé County, in the interior of the Gaspe peninsula. This has provided evidence to substantiate the belief that the rocks in which the specimen was found are of Middle Devonian age. Dr. F. J. Alcock, of the Geological Survey of Canada, presented evidence based on the findings of several striated surfaces and many erratics in central Gaspe which support his already published conclusions that the Labrador ice sheet crossed the Shickshock Mountains. Dr. J. S. DeLury, professor of geology and mineralogy in the University of Manitoba, was elected president of the Section, and Dr. B. R. MacKay, of Ottawa, vice-president.

Dr. H. S. Jackson, University of Toronto, President of Section V, spoke on "Life Cycles and Phylogeny in the Higher Fungi". The discussion centred in a comparison of life-cycles in the rusts with those in the red algæ. It was shown that not only do the normal cycles correspond very closely, but that the same sort of simplified cycles occur in both groups. A life-cycle comparable to that of the ascomycetes also occurs among the simplified red algæ.

Prof. Velyien Henderson, the Flavelle Medal winner, presented a paper by invitation entitled "Studies in Anaesthesia with the Cyclopropane Group". Prof. A. T. Cameron, professor of biochemistry in the University of Manitoba, outlined the results of his researches on the relative sweetness of certain sugars and mixtures of sugar. If a solution

contains known concentrations of two or more sugars, a means has been found for calculating the sweetness of this mixture in terms of that of a specific concentration of sucrose or of glucose. It has been demonstrated that the sweetness of 25 per cent sucrose is not more than (and is probably less than) 3·3 times that of 5 per cent sucrose. Forty-three other papers on various phases of biological and medical sciences made up the programme of Section V. Dr. Robert Newton, president and formerly professor of plant biochemistry in the University of Alberta, is the new president of the Section and Prof. B. P. Babkin, research professor of physiology in McGill University, vice-president.

Prof. J. K. Robertson, professor of physics in the Queen's University, Kingston, Ontario, is the new president of the Society, and Prof. E. S. Moore, professor of geology in the University of Toronto, vice-president.

J. R. DYMOND.

# THE ROYAL OBSERVATORY, GREENWICH

## ANNUAL REPORT

THE annual report of the Astronomer Royal to the Board of Visitors covers the period May 1, 1943–April 30, 1944, and describes the work done during the year at Greenwich and the various out-stations which together constitute the war-time Royal Observatory. Until the last-named date, no further damage by enemy action had been sustained at Greenwich. On the observational side, a restricted astronomical programme on the Airy transit circle has been maintained, solar work has been continued on the photoheliograph and spectrohelioscope, and the routine meteorological observations have been made as in normal times. Work at the out-stations includes the maintenance and improvement of the time service, which still operates from two undisclosed locations, the rating and supply of chronometers and watches for use in H.M. Forces, the production of the *Nautical Almanac* and various ancillary publications, and the regular magnetic observations made, as in previous years, at Abinger.

Fundamental observations of position made on the Airy transit circle include about a thousand transits of stars, the sun, and the planets. Collimation observations, which have hitherto been possible only in daylight and then only with difficulty, are now facilitated by artificial illumination. A surprising feature revealed by the level observations of the last twenty-one years is that in that time the east pier of the instrument has steadily sunk by about $\frac{1}{12}$ in. relative to the west pier, though no such subsidence had occurred before in the seventy-two years of its previous history.

A discussion of the preliminary tests on the new reversible transit circle, based on observations made between its installation in 1936 and 1940, shows that the annual variations in level and azimuth are satisfactorily small. The diurnal changes in azimuth are small; those in level are of more consequence but can be reduced by better lagging of the piers; but those in collimation are disconcertingly large when the ambient temperature is unsteady. At present there seems no escape from the conclusion that a large amount of observing time must be used on observations of collimation in order to provide a satisfactory control of the variations. Latitude results on the Cookson floating zenith telescope relating to the period 1936–40 have also been derived, and the observations are examined with the view of tracing to their source the occasional large residuals shown, especially by recent observations. No certain conclusion is reached, though anomalous surface tension effects and wind effects are suspected.

The solar work calls for little comment. Sunspot frequency has slowly fallen, no spots being recorded at all during February, and only one very small spot during April. The epoch of minimum activity has apparently been reached, and the first high-latitude spots of the new cycle appeared in May 1943. Geomagnetic activity was considerable, however: one great storm and twenty smaller ones occurred, some of these latter falling in a 27-day cycle characteristic of storms at solar minimum. It is surprising that one of the five short-wave radio fade-outs which occurred during the year did so when no spot was visible on the disk. Fade-outs of this type have hitherto been attributed to solar flares ('chromospheric eruptions'), which are associated almost exclusively with sunspots. It will be interesting if positive spectroscopic evidence can be obtained that this is an instance of a flare occurring unassociated with a spot.

The Nautical Almanac Office continues its routine computational work involved in the production of the *Nautical Almanac*, the *Abridged Nautical Almanac*, the *Air Almanac* and the *Astronomical Navigation Tables*. A large increase in the work of the Office has occurred, and still more is forecast, as a result of the formation of the Admiralty Computing Service early in 1943. The Nautical Almanac Office forms the nucleus of this body, performing all the centralized computing and advising on tables, methods and machines. Some forty pieces of computation have been undertaken, none of them of an astronomical character, and about half of them have already been completed.

A major section of the Astronomer Royal's report is devoted to the work of the Time Department, which is evidently still expanding rapidly. The time service has been operated, as in previous years, from duplicate stations, each a self-contained unit itself capable of providing the whole service. The change-over from pendulum clocks to quartz crystal clocks, forecast in the last report, is now under way. Three quartz clocks have been installed during the year, one at each station being equipped with a phonic motor having a 60 : 61 gearing to provide the vernier time signals. These signals are now operated solely from phonic motors, and the accuracy of spacing of the signal pulses has greatly improved. Errors of as much as five milliseconds due to the unfortunate habit of pendulum clocks of 'wandering' between final correction and signal transmission have also been eliminated by this substitution. The new clocks are not yet used as primary standards, since the quartz crystals are not sufficiently 'aged', so the long-term performance of the time service has not yet been materially improved by their installation. But in short-term performance a marked improvement has already occurred: the uncertainty of individual 24-hour intervals defined by successive $10^h$ GBR signals has decreased from $\pm 5$ to $\pm 1{\cdot}2$ parts in $10^8$. Improvements in long-term performance are predicted for the near future as a result, first, of the transference to floating-battery operation of the primary standards maintained outside the Observatory (their performance has hitherto suffered from

mains failures); and, secondly, of the eventual incorporation among the primaries of the quartz clocks newly installed, and others to be installed, at the Observatory. After that, improvements in the time service will depend not so much on horological developments as on improvement of the astronomical observations. Although minor improvements are possible in the standard small transit instruments at present in use (an optical autocollimation method of level determination is mentioned), their supersession by a photographic reflex zenith tube is forecast by the Astronomer Royal, and preparations for the new telescope are already at the design stage. The Admiralty has sanctioned construction of an instrument of aperture 10 in. and focal length 11 ft. 3 in., giving a scale of 1 minute of arc to 1 mm., and the main details have already been settled. This instrument should improve materially the accuracy of the time determinations. Together with the purely horological developments reported and forecast in this report, it should make possible the provision in the future of a time service equal to all the exacting demands made upon it, and second to none in the world.

## CARNEGIE INSTITUTION OF WASHINGTON

### ANNUAL REPORT

THE Year Book No. 42 of the Carnegie Institution of Washington, covering the year July 1, 1942–June 30, 1943, includes the reports of the Executive Committee, the auditors, and of the president, together with reports of departmental activities and co-operative studies. The president's report points out that although the total research effort of the Institution is more than twice as great as in the year just prior to the War, the efforts of the research staff are now so largely devoted to war research that the regular programmes have been severely curtailed. The services of seventy members of the Institution staff have been loaned for war work in other organizations. The Geophysical Laboratory is now completely devoted to a war programme for which its facilities and staff are specially fitted, and the Department of Terrestrial Magnetism is similarly occupied. The Mount Wilson Observatory has several important programmes under way utilizing the special knowledge of astronomers and physicists, and the war effort continues to demand more outstanding talent in the physical sciences than is available and to utilize to a lesser extent men from the biological sciences.

Investigations of the Division of Plant Biology referred to in the report are those on the biochemistry of algæ, including the selection and isolation of algæ, their pigments, effects of environment on their pigment content, and the production of organic matter by *Chlorella pyrenoidosa*. Investigations on the nature of substances produced directly by photosynthesis in sunflower leaves have continued, and improved methods of pigment analysis have been developed which show promise of application to other fields of chemical and biochemical investigation. In addition to investigations on the breeding of new forage grasses of importance for food production, excellent progress is reported in the normal programmes of biochemical investigation and experimental taxonomy. In the Department of Genetics, research in endocrinology, especially in regard to the action of the parathyroid gland, is being completed, and an interesting mutation in mice which aids in interpreting certain processes of normal development is being studied. Other investigations concern broken chromosomes in maize, the genetics of the mouse, hormone action in carbohydrate and fat metabolism, the effects of ultra-violet radiation on mitosis, radiation theory and breeding studies on the Russian dandelion.

At the Mount Wilson Observatory the remarkable reversal of sign of magnetic polarity characteristic of a new solar cycle has been fully confirmed. Advances in the efficiency of the stellar spectrographs have led to notable discoveries regarding the structure of the expanding shells surrounding the novæ of our galactic system and have aided in the interpretation of these objects. The discovery of a shell round the novæ in Auriga of 1891 is of exceptional interest. The powerful spectrographs in use with the 100-in. telescope have opened new fields in the analysis of stellar spectra, and in the study of differential motions in the stellar atmospheres, and of the distribution and composition of the gaseous clouds of interstellar space. The cyclotron at the Department of Terrestrial Magnetism has been completed, and cosmic data were assembled and analysed to increase the understanding of solar geomagnetic and ionospheric relations and to improve the technique of short-term forecasting of ionospheric disturbances. The value of the ionospheric programme undertaken by the Department has been emphasized by the urgent need of particulars regarding the relations of ionospheric variations and disturbances and the many confidential studies for operational application which have been made. Tables of changes in the annual mean value of the geomagnetic field with sunspot cycle, the average annual variations, daily post-perturbations and average solar daily variations for the period 1905–42 were nearly completed.

The final section of the president's report considers the broad problem of the status of scientific research in the United States after the War and the unique position of the Institution. The importance of independent scientific bodies such as the Carnegie Institution in the pattern of scientific research likely to develop after the War is emphasized, and in a frank discussion of the probable endowment position of research generally as between the universities, the Government, and independent scientific institutions, the necessity of studying the trends carefully is stressed.

## *DROSOPHILA MELANOGASTER*

THE American fruit fly holds a unique position in biology; this animal has probably been more intensively studied from all angles of biology than any other. The immense literature and specialized language illustrates the intensity of attention it has received. Yet some geneticists, and a much smaller proportion of botanists and zoologists, know very little of the results of this intense experimentation. It was understandable that during its early years of captivity it should be of particular interest for the development of the chromosome theory of heredity. As a consequence the excuse that it was a laboratory plaything might be considered to be reasonable.

Since that time, however, this Drosophila has provided most important data in subjects which are considered to be the province of the taxonomist, ecologist and morphologist.

Its intrinsic value as an organism about which we know more of its heritable characters than of any other living thing gives Drosophila a position which cannot be ignored when discussing the evolutionary problems and behaviour of organisms in the wild. The 'drosophilists' have realized the importance of wild population studies and are providing and accumulating many data in the United States.

It is fortunate that two monographs have just been issued[1,2] under the names of the late Dr. C. Bridges and Dr. K. S. Brehme, and Prof. J. T. Patterson, respectively. The first is a valuable and possibly classical work on the known characters of Drosophila. After listing the symbolization used in Drosophila literature in a form comprehensible to an ordinary geneticist, the inherited characters are described, together with the positions of the related genes on the chromosomes, their origins and authorities. These data, included in two hundred pages, are followed by chromosome maps of the genes which leave all other published maps far behind. A fitting conclusion to the publication is the inclusion of the salivary chromosome maps originally published in the *Journal of Heredity*. The conception of this work was designed by Dr. M. Demerec, director of the Carnegie Institution, and with the co-operation of many geneticists the compilation by Dr. Brehme is a fitting memorial to Dr. Bridges. This publication gives the biologist an accurate description of the genetic characters of *Drosophila melanogaster*.

The publication by Patterson and his co-workers carries, as it were, the attack into the enemy's camp. Here the species of Drosophila which have been found in the south-west of the United States and Mexico are described with the meticulous care of the systematist, and each is illustrated with coloured plates. Twenty-four new forms are described for the first time, while numerous data from collecting work provides an insight into geographical distribution and reasons for the fluctuations in numbers in wild populations. J. T. Patterson and R. P. Wagner consider the distribution of the species of Drosophila throughout the United States and give data on the reactions of different species to ecological factors. L. J. Wharton describes the metaphase complements and the salivary gland chromosomes of eighty Drosophila species.

As a result of these investigations on an animal the genetical constitution of which is better known than that of any other, it is possible to raise doubts and to call for reconsideration of important current and established theories, some of which are keystones in branches of biology. For example, it is clearly seen that homology between parts of chromosomes in related species cannot be assumed without hybridization experiments and linkage studies. Similar characters in different species may depend on different genic origins. This being so, to what extent can homology of characters in different organisms be utilized as has been done in the past by morphologists as a criterion in evolution? Does the different origin and development of a character affect the validity of the evidence derived from analysing such characters in different phyla?

Again, there is strong evidence in Drosophila that phylogenetic relationships based on metaphase chromosome idiograms may be invalid unless supported by salivary gland chromosome analysis or cross-over configurations and other genetical criteria.

On the problem of speciation, the distribution of the species of Drosophila in the United States is interesting. A very few species are widespread while a larger number of species, many of which are local, are found in areas where there is great environmental diversity.

The reviewer is impressed by the painstaking work, the absence of contentious or other theories and the manner in which the solid results become related into a coherent whole. The evidence touches on many fields of biology and it is salutary, and we believe necessary, to consider it in relation to current theories in different branches of botany and zoology.

## SUMERIAN MYTHOLOGY*

TO-DAY everyone in the least interested in archæology has heard of the Sumerian culture of Mesopotamia and the cuneiform system of writing that was developed there. Not everyone realizes that only so recently as 1850 was the existence of this all-important non-Indo-European and non-Semitic people so much as suspected. Nowadays, of course, the Sumerians take pride of place as the dominant cultural element in Mesopotamia from the fourth to nearly the beginning of the second millennium B.C., and the influence of their culture is known to have spread far and wide and to have lasted long after the folk themselves had been swamped by their Semitic neighbours. Why are there to-day sixty seconds in a minute, sixty minutes in an hour, and $6 \times 60$ degrees in a circle? Because the Sumerians used a unit of sixty. Their unit of weight, the mina, seems to have been just about equal to the Imperial pound.

The Sumerians used tablets of clay to write on, and many thousands of these have turned up in the course of excavations. More particularly is this true of the American excavations at Nippur, which were carried on at intervals between 1889 and 1900. But the writing is difficult to interpret and much of the material is broken; and in consequence a great deal still remains to be deciphered. Most of the quarter of a million or so tablets that have been unearthed are concerned with matters of business, but a small proportion, dating mostly to about 2000 B.C., can be classed as 'literary' tablets, and these are inscribed with Sumerian epics, myths, hymns, lamentations, proverbs and words of wisdom. There are also a number inscribed with mathematical texts and incantations Mr. S. N. Kramer is concerned to publish much of this hitherto undeciphered material in a number of volumes, of which this one on Sumerian mythology is the first. He has had the opportunity of working for nearly two years at the Nippur collections now in Turkey, as well as at those from the same site now housed in the United States. This first volume is extremely well put together and illustrated. It does not assume a greater knowledge of Mesopotamian

* Memoirs of the American Philosophical Society. Vol. 21: Sumerian Mythology, a Study of Spiritual and Literary Achievement in the Third Millennium B.C. Pp. xiv+125+21 plates. By S. N. Kramer. (Philadelphia, 1944.)

archæology than can be obtained from any one of the well-known manuals.

After an explanatory preface and an introduction there is a chapter on the scope and significance of Sumerian mythology. This is followed by an account of the myths of origins, of Kur and the slaying of the dragon, of the deluge—antedating, of course, the well-known Neo-Babylonian epic—of the marriage of the god Martu, and of the preference of Inanna, sister of the sun-god Utu, for the farmer-god Enkimdu over the shepherd-god Dumuzi: a pretty story which ends with the seeming victory of Dumuzi over Enkimdu.

These Sumerian 'literary' tablets are some centuries older than the Neo-Babylonian epics, and borrowing by these can be detected. They are also about six hundred years older than the somewhat similar material which is turning up at Ras Shamra in northern Syria. Contact in Mesopotamia between the intrusive, matter-of-fact Sumerian folk of unknown racial affinity and their Semitic neighbours seems to have resulted in the development of epics, myths and proverbs which have proved a veritable mine into which later cultures have delved when they in turn set themselves to answer such problems as the origin of the world and man. It is to be hoped the subsequent volumes will appear without undue delay. M. C. BURKITT.

## FORTHCOMING EVENTS

### Tuesday, September 5

WOMEN'S ENGINEERING SOCIETY (MANCHESTER BRANCH) (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Mr. E. T. Norris: "The Moving Coil Voltage Regulator".

### Friday, September 8

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Sir Harold Spencer Jones, F.R.S., and Mr. R. T. Cullen: "The Division Errors of the Reversible Transit Circle of the Royal Observatory, Greenwich"; Mr. C. S. Beals: "Some Results of a Spectrophotometric Study of the Wolf Rayet Binary HD 193576"; Mr. D. L. Edwards: "Periodic Changes in $\gamma$ Cassiopeiae during the past 100 Years".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

UNIVERSITY READERSHIP IN PHYSICS tenable at King's College—The Academic Registrar, University of London, South Kensington, London, S.W.7 (September 6).

HEAD OF THE DEPARTMENT OF PRODUCTION ENGINEERING—The Principal, Leicester College of Technology and Commerce, Leicester (September 9).

LECTURER IN CHEMISTRY—The Registrar, Technical College, Sunderland (September 9).

CHIEF ENGINEER by large firm of Locomotive Manufacturers—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2243.XA) (September 11).

SPEECH THERAPIST—The Director of Education, Education Offices, 15 John Street, Sunderland (September 15).

TECHNICAL EDITOR of the *Electrical Power Engineer* and DIRECTOR OF STUDIES of the Correspondence Tuition Scheme of the Association—The General Secretary, Electrical Power Engineers' Association, 102 St. George's Square, London, S.W.1 (endorsed 'Technical Editor') (September 15).

UNIVERSITY READERSHIP IN CHEMISTRY tenable at the Royal Cancer Hospital (Free)—The Academic Registrar, University of London, South Kensington, London, S.W.7 (September 18).

RESPONSIBLE LECTURER IN PHYSIOLOGY—The Principal, Chelsea Polytechnic, Manresa Road, London, S.W.3 (September 20).

CHAIR OF MINING—The Acting Registrar, The University, Leeds 2 (September 30).

DIRECTOR OF RESEARCH, Forest Products Research Laboratory, Princes Risborough—The Secretary, Department of Scientific and Industrial Research, Teddington, Middx. (October 9).

LECTURER IN PHILOSOPHY—The Very Rev. the Dean, Christ Church, Oxford (October 15).

DIRECTOR OF THE DEPARTMENT OF SOCIAL STUDIES, University of Sydney—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, London, W.C.1 (Sydney, December 1).

SECOND VETERINARY OFFICER at the Imperial Bureau of Animal Health, Weybridge—The Secretary, Imperial Agricultural Bureaux, 2 Queen Anne's Gate Buildings, London, S.W.1.

ASSISTANT MASTER (temporary) qualified to teach ENGINEERING SUBJECTS and MATHEMATICS up to Ordinary National Certificate standard—The Principal, Technical Institute, Beckenham Road, Beckenham, Kent.

BOTANIST AND ORGANIC CHEMIST to the Nyasaland Research and Development Co., Ltd.—Dr. M. Nierenstein, 2 Rylestone Grove, Bristol 9.
